Chapter 2: Application Layer

Applications

... built on ...

Reliable (or unreliable) transport

... built on ...

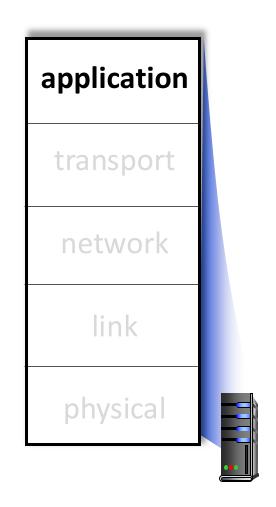

Best-effort global packet delivery

... built on ...

Best-effort local packet delivery

... built on ...

Physical transfer of bits

The source PowerPoint slides are public available, provided by Authors (JFK/KWR). They are revised for CS536@Purdue.

Application layer: goals

- conceptual, implementation aspects of network application protocols
 - transport-layer service models
 - client-server paradigm
 - peer-to-peer paradigm

- learn about protocols by examining popular applicationlevel protocols
 - HTTP
 - SMTP / POP3 / IMAP
 - DNS
 - P2P
 - Video streaming
- creating network applications
 - socket API

Application layer: overview

- Principles of network applications
- Web and HTTP
- E-mail, SMTP, IMAP
- The Domain Name System DNS

- P2P applications
- video streaming and content distribution networks
- socket programming with UDP and TCP

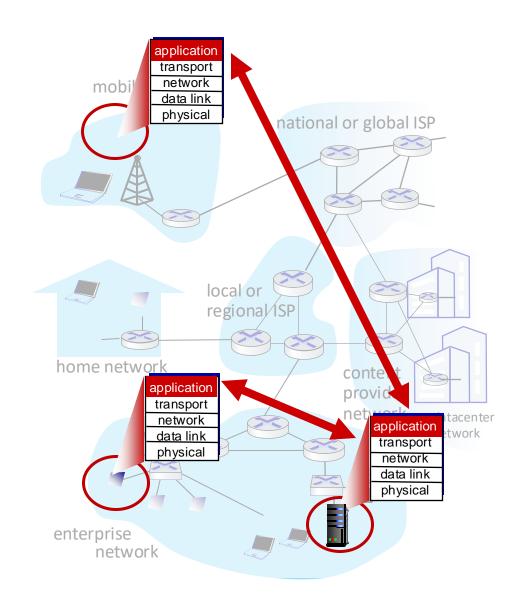

Creating a network app

write programs that:

- run on (different) end systems
- communicate over network
- e.g., web server software communicates with browser software

no need to write software for network-core devices

- network-core devices do not run user applications
- applications on end systems allows for rapid app development, propagation

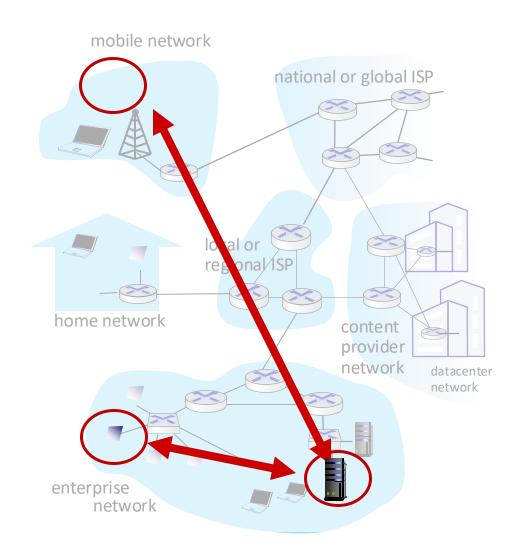

Client-server paradigm

server:

- always-on host
- permanent IP address
- often in data centers, for scaling

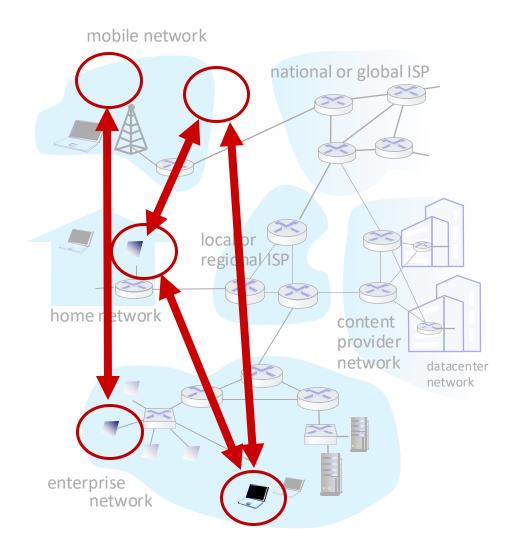

clients:

- contact, communicate with server
- may be intermittently connected
- may have dynamic IP addresses
- do not communicate directly with each other
- examples: HTTP, IMAP, FTP

Peer-peer architecture

- no always-on server
- arbitrary end systems directly communicate
- peers request service from other peers, provide service in return to other peers
 - self scalability new peers bring new service capacity, as well as new service demands
- peers are intermittently connected and change IP addresses
 - complex management
- example: P2P file sharing

Processes communicating

process: program running
 within a host

- within same host, two processes communicate using inter-process communication (defined by OS)
- processes in different hosts communicate by exchanging messages

- clients, servers

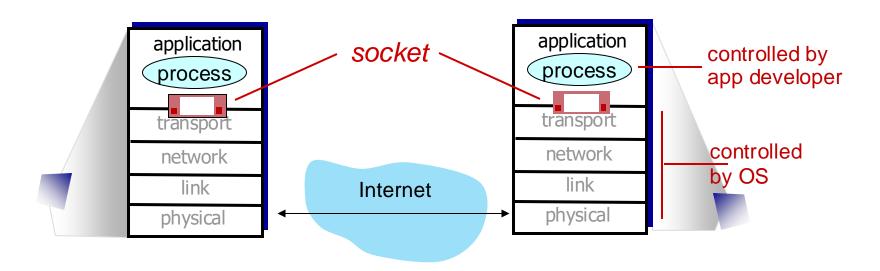

client process: process that initiates communication

server process: process that waits to be contacted

 note: applications with P2P architectures have client processes & server processes

Sockets

- process sends/receives messages to/from its socket
- socket analogous to door
 - sending process shoves message out door
 - sending process relies on transport infrastructure on other side of door to deliver message to socket at receiving process
 - two sockets involved: one on each side

Addressing processes

- to receive messages, process must have identifier
- host device has unique 32-bit IP address
- Q: does IP address of host on which process runs suffice for identifying the process?
 - A: no, many processes can be running on same host

- identifier includes both IP address and port numbers associated with process on host.
- Example port numbers:
 - HTTP server: 80
 - mail server: 25
- Example: to send HTTP message to google.com web server:
 - IP address: 142.250.191.100
 - port number: 80
- more shortly...

An application-layer protocol defines:

- types of messages exchanged,
 - e.g., request, response
- message syntax:
 - what fields in messages & how fields are delineated
- message semantics
 - meaning of information in fields
- rules for when and how processes send & respond to messages

open protocols:

- defined in RFCs, everyone has access to protocol definition
- allows for interoperability
- e.g., HTTP, SMTP

proprietary protocols:

e.g., Skype, Zoom

What transport service does an app need?

data integrity

- some apps (e.g., file transfer, web transactions) require
 100% reliable data transfer
- other apps (e.g., audio) can tolerate some loss

timing

 some apps (e.g., Internet telephony, interactive games) require low delay to be "effective"

throughput

- some apps (e.g., multimedia) require minimum amount of throughput to be "effective"
- other apps ("elastic apps")
 make use of whatever
 throughput they get

security

encryption, data integrity,...

Transport service requirements: common apps

	application	data loss	throughput	time sensitive?
file transfer/download		no loss	elastic	no
	e-mail	no loss	elastic	no
Web	documents	no loss	elastic	no
real-time	audio/video	loss-tolerant	audio: 5Kbps-1Mbps video:10Kbps-5Mbps	yes, 10's msec
streaming	audio/video	loss-tolerant	same as above	yes, few secs
intera	ctive games	loss-tolerant	Kbps+	yes, 10's msec
tex	t messaging	no loss	elastic	yes and no

Internet transport protocols services

TCP service:

- reliable transport between sending and receiving process
- *flow control:* sender won't overwhelm receiver
- congestion control: throttle sender when network overloaded
- connection-oriented: setup required between client and server processes
- does not provide: timing, minimum throughput guarantee, security

UDP service:

- unreliable data transfer
 between sending and receiving process
- does not provide: reliability, flow control, congestion control, timing, throughput guarantee, security, or connection setup.

Q: why bother? Why is there a UDP?

Internet applications, and transport protocols

application	application layer protocol	transport protocol
file transfer/download	FTP [RFC 959]	TCP
e-mail	SMTP [RFC 5321]	TCP
Web documents	HTTP 1.1 [RFC 7320]	TCP
Internet telephony	SIP [RFC 3261], RTP [RFC 3550], or proprietary	TCP or UDP
streaming audio/video	HTTP [RFC 7320], DASH	TCP
interactive games	WOW, FPS (proprietary)	UDP or TCP

Application layer: overview

- Principles of network applications
- Web and HTTP
- E-mail, SMTP, IMAP
- The Domain Name System DNS

- P2P applications
- video streaming and content distribution networks
- socket programming with UDP and TCP

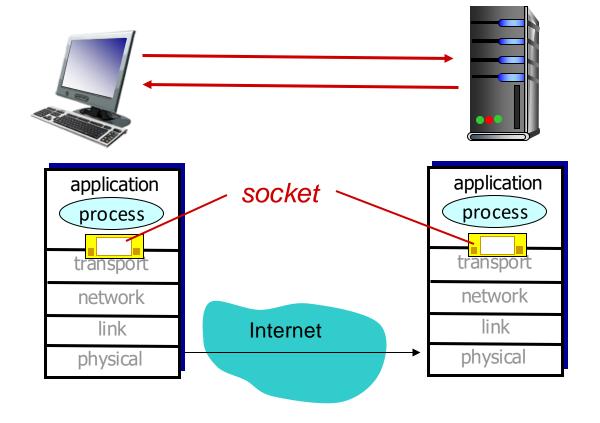

Web and HTTP

• Most popular or a killer application on the Internet

4 Questions in Web and HTTP

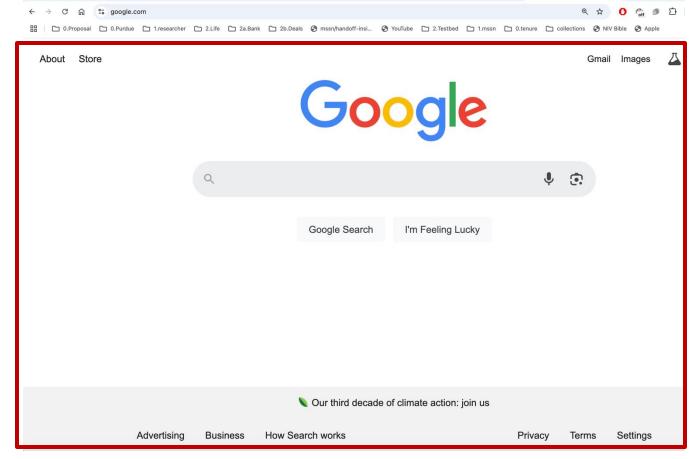

- What content to transfer?
 - Web pages
- How to transfer?
 - HTTP connections
- In what messages?
 - HTTP messages
- Advanced features

Web and Web browser

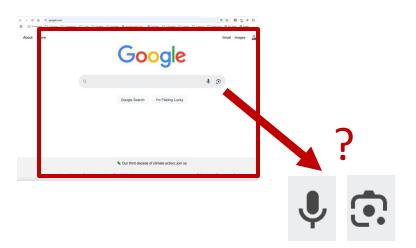

- On the client
 - Loading web pages in web browser

A web page for www.google.com (right-click: view source)

Web page source (example)

```
<!doctype html>
        <html itemscope=""
itemtype="http://schema.org/WebPage" lang="en">
        <head>
                 <meta charset="UTF-8">
                 <meta content="origin"
name="referrer"><meta
content="Anm+hhtuh7NJguqSnXHEAlqqMaV+GXCks8WYXHJKF7l6A

W4iOiJodHRwczovL2dvb2dsZS5jb206NDQzIiwiZmVhdHVyZSI6IIByaX
ZhY3lTYW5kYm94QWRzQVBJcyIsImV4cGlyeSI6MTY5NTE2Nzk5OSwi
aXNTdWJkb21haW4iOnRydWV9" http-equiv="origin-trial">
<meta
content="/images/branding/googleg/1x/googleg_standard_color_1
28dp.png" itemprop="image"><title>Google</title><script
nonce="JJKfRqtwMmdETGNCuWyfCA">window._hst=Date.now();</
script><script nonce="JJKfRqtwMmdETGNCuWyfCA">(function()
```

https://www.google.com/images/branding/googleg/ 1x/googleg_standard_color_128dp.pngApplication Layer: 2-20

Web page

First, a quick review...

- web page consists of objects, each of which can be stored on different Web servers
- object can be HTML file, JPEG image, Java applet, audio file,...
- web page consists of base HTML-file which includes several referenced objects, each addressable by a URL, e.g.,

http://www.google.com /images/b

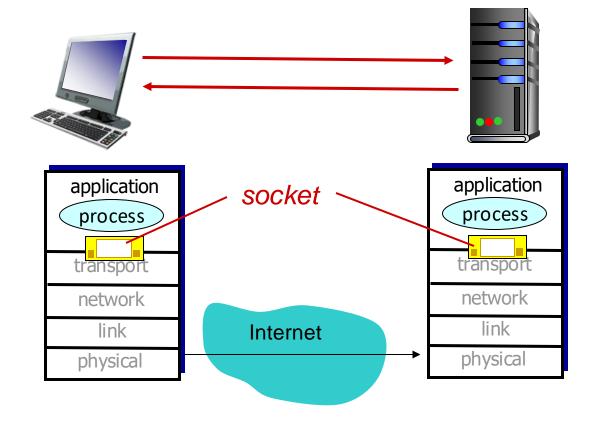

/images/branding/googleg/1x/googleg_standard_color_128dp.png

host name

path name

4 Questions in Web and HTTP

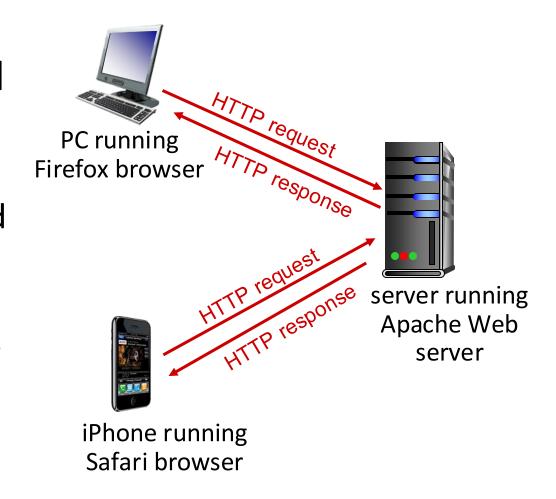

- What content to transfer?
 - Web pages
- How to transfer?
 - HTTP connections
- In what messages?
 - HTTP messages
- Advanced features

HTTP overview

HTTP: hypertext transfer protocol

- Web's application-layer protocol
- client/server model:
 - client: browser that requests, receives, (using HTTP protocol) and "displays" Web objects
 - server: Web server sends (using HTTP protocol) objects in response to requests

HTTP overview (continued)

HTTP uses TCP:

- client initiates TCP connection (creates socket) to server, port 80
- server accepts TCP connection from client
- HTTP messages (application-layer protocol messages) exchanged between browser (HTTP client) and Web server (HTTP server)
- TCP connection closed

HTTP is "stateless"

 server maintains no information about past client requests

aside

protocols that maintain "state" are complex!

- past history (state) must be maintained
- if server/client crashes, their views of "state" may be inconsistent, must be reconciled

HTTP connections: two types

Non-persistent HTTP

- 1. TCP connection opened
- 2. at most one object sent over TCP connection
- 3. TCP connection closed

downloading multiple objects required multiple connections

Persistent HTTP

- TCP connection opened to a server
- multiple objects can be sent over single TCP connection between client, and that server
- TCP connection closed

Non-persistent HTTP: example

User enters URL: www.someSchool.edu/someDepartment/home.index (containing text, references to 10 jpeg images)

- 1a. HTTP client initiates TCP connection to HTTP server
 - (process) at www.someSchool.edu on port 80
 - 2. HTTP client sends HTTP request message (containing URL) into TCP connection socket. Message indicates that client wants object someDepartment/home.index

- 1b. HTTP server at host www.someSchool.edu waiting for TCP connection at port 80 "accepts" connection, notifying client
 - 3. HTTP server receives request message, forms *response message* containing requested object, and sends message into its socket

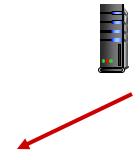

time

Non-persistent HTTP: example (cont.)

User enters URL: www.someSchool.edu/someDepartment/home.index (containing text, references to 10 jpeg images)

5. HTTP client receives response message containing html file, displays html. Parsing html file, finds 10 referenced jpeg objects

4. HTTP server closes TCP connection.

6. Steps 1-5 repeated for each of 10 jpeg objects

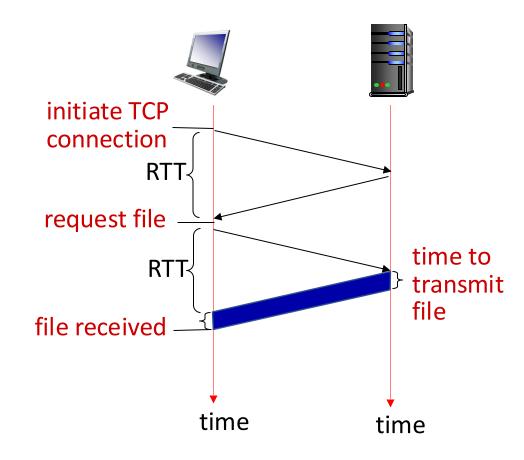

Non-persistent HTTP: response time

RTT (definition): time for a small packet to travel from client to server and back

HTTP response time (per object):

- one RTT to initiate TCP connection
- one RTT for HTTP request and first few bytes of HTTP response to return
- object/file transmission time

Non-persistent HTTP response time = 2RTT+ file transmission time

Persistent HTTP (HTTP 1.1)

Non-persistent HTTP issues:

- requires 2 RTTs per object
- OS overhead for each TCP connection
- browsers often open multiple parallel TCP connections to fetch referenced objects in parallel

Persistent HTTP (HTTP1.1):

- server leaves connection open after sending response
- subsequent HTTP messages between same client/server sent over open connection
- client sends requests as soon as it encounters a referenced object
- as little as one RTT for all the referenced objects (cutting response time in half)

Non-persistent HTTP vs. persistent HTTP

- A web page with 10 image objects. How long to complete all?
 - Ignore the object transmission time
 - non-persistent HTTP (with 1 object one time)

```
22 RTTs = 2RTTs \times (1 + 10) (2 RTTs for base HTML file,
```

Persistent HTTP

2 RTTs per object)

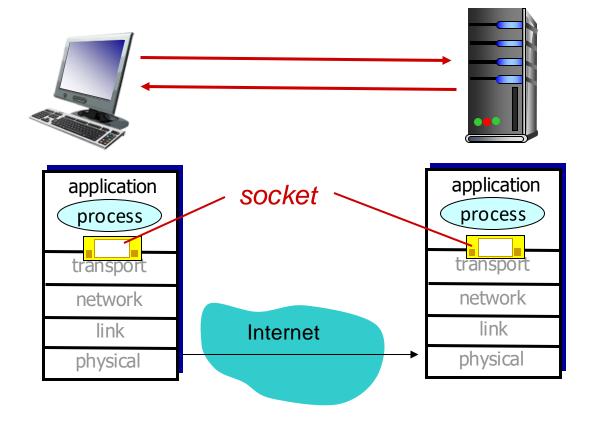

```
12 RTTs = 2RTTs + 10 RTTs (1 RTT per object)
```

non-persistent HTTP (5 objects in parallel)

```
6RTTs = 2RTTs + 2RTTs + 2RTTs (2 RTTs for base html file,
2 more RTTs for the first 5 objects
2 more RTTs for the last 5 objects)
```

4 Questions in Web and HTTP

- What content to transfer?
 - Web pages
- How to transfer?
 - HTTP connections
- In what messages?
 - HTTP messages
- Advanced features

HTTP request message

- two types of HTTP messages: request, response
- HTTP request message:
 - ASCII (human-readable format)

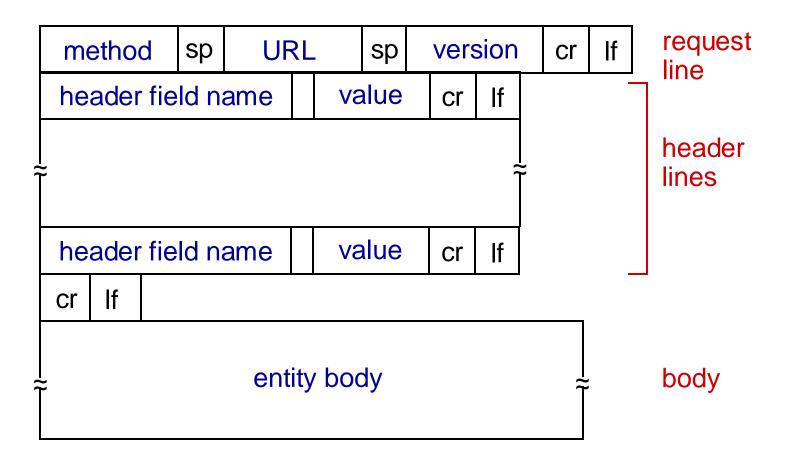

```
request line (GET, POST, HEAD commands)
```

carriage return character line-feed character

carriage return, line τeeα — at start of line indicates end of header lines

^{*} Check out the online interactive exercises for more examples: http://gaia.cs.umass.edu/kurose_ross/interactive/

HTTP request message: general format

Other HTTP request messages

POST method:

- web page often includes form input
- user input sent from client to server in entity body of HTTP POST request message

GET method (for sending data to server):

 include user data in URL field of HTTP GET request message (following a '?'):

www.somesite.com/animalsearch?monkeys&banana

HEAD method:

 requests headers (only) that would be returned if specified URL were requested with an HTTP GET method.

PUT method:

- uploads new file (object) to server
- completely replaces file that exists at specified URL with content in entity body of POST HTTP request message

Demo: try out HTTP (client side) for yourself

1. netcat to your favorite Web server:

% nc -c -v gaia.cs.umass.edu 80

% telnet gaia.cs.umass.edu 80

- opens TCP connection to port 80 (default HTTP server port) at gaia.cs.umass. edu.
- anything typed in will be sent to port 80 at gaia.cs.umass.edu

2. type in a GET HTTP request:

GET /kurose_ross/interactive/index.php HTTP/1.1

Host: gaia.cs.umass.edu

- by typing this in (hit carriage return twice), you send this minimal (but complete) GET request to HTTP server
- 3. look at response message sent by HTTP server!

(or use Wireshark to look at captured HTTP request/response)

HTTP response message

HTTP response status codes

- status code appears in 1st line in server-to-client response message.
- some sample codes:

200 OK

request succeeded, requested object later in this message

301 Moved Permanently

 requested object moved, new location specified later in this message (in Location: field)

400 Bad Request

request msg not understood by server

404 Not Found

requested document not found on this server

505 HTTP Version Not Supported

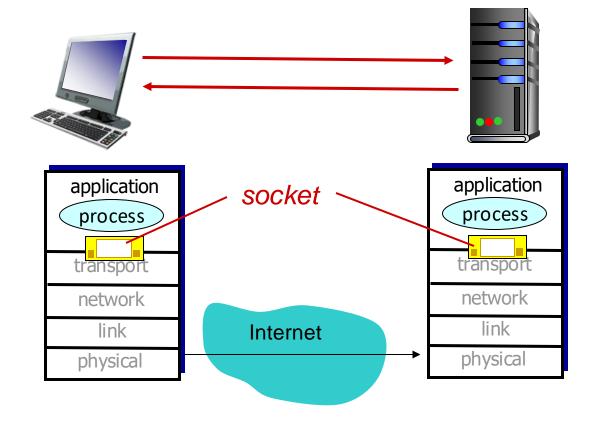

HTTP response status codes (more, optional)

- 1xx: Informational means the request was received and the process is continuing.
- 2xx: Success means the action was successfully received, understood, and accepted.
- 3xx: Redirection means further action must be taken in order to complete the request.
- 4xx: Client ErrorIt means the request contains incorrect syntax or cannot be fulfilled.
- 5xx: Server Error means the server failed to fulfill an apparently valid request.

Reference: https://www.tutorialspoint.com/http/http responses.htm
Reference of 200 OK status: https://restfulapi.net/http-status-200-ok/

4 Questions in Web and HTTP

- What content to transfer?
 - Web pages
- How to transfer?
 - HTTP connections
- In what messages?
 - HTTP messages
- Advanced features

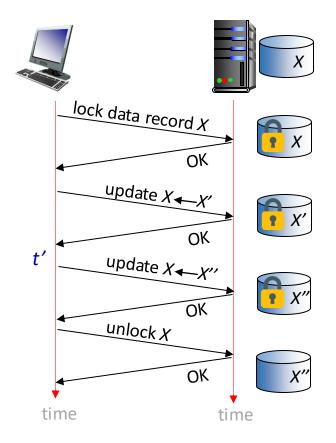

Maintaining user/server state: cookies

Recall: HTTP GET/response interaction is *stateless*

- no notion of multi-step exchanges of HTTP messages to complete a Web "transaction"
 - no need for client/server to track "state" of multi-step exchange
 - all HTTP requests are independent of each other
 - no need for client/server to "recover" from a partially-completed-but-nevercompletely-completed transaction

a stateful protocol: client makes two changes to X, or none at all

Q: what happens if network connection or client crashes at t'?

Maintaining user/server state: cookies

Web sites and client browser use cookies to maintain some state between transactions

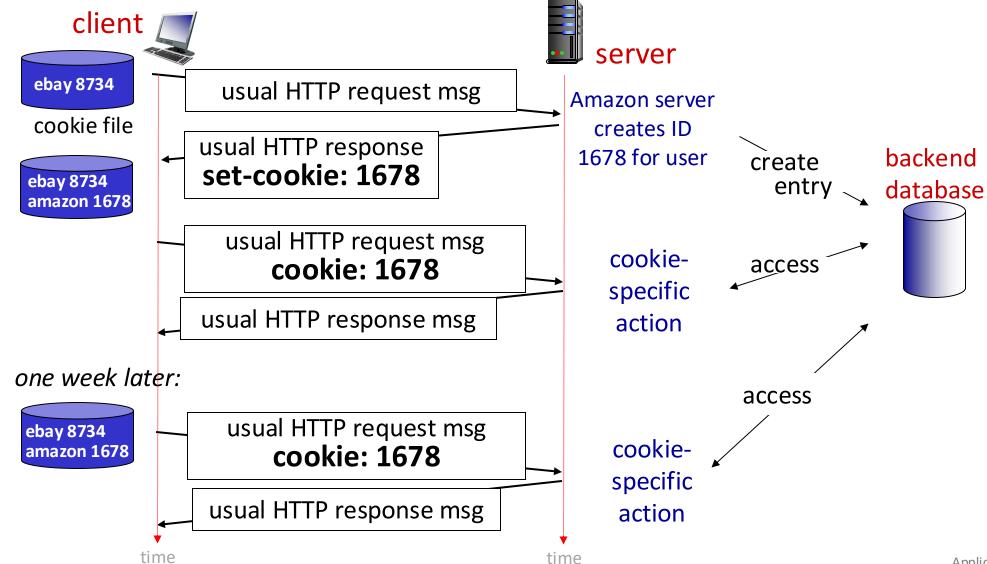

four components:

- 1) cookie header line of HTTP *response* message
- 2) cookie header line in next HTTP request message
- 3) cookie file kept on user's host, managed by user's browser
- 4) back-end database at Web site

Example:

- Susan uses browser on laptop, visits specific e-commerce site for first time
- when initial HTTP requests arrives at site, site creates:
 - unique ID (aka "cookie")
 - entry in backend database for ID
- subsequent HTTP requests from Susan to this site will contain cookie ID value, allowing site to "identify" Susan

Maintaining user/server state: cookies

HTTP cookies: comments

What cookies can be used for:

- authorization
- shopping carts
- recommendations
- user session state (Web e-mail)

Challenge: How to keep state?

- at protocol endpoints: maintain state at sender/receiver over multiple transactions
- in messages: cookies inHTTP messages carry state

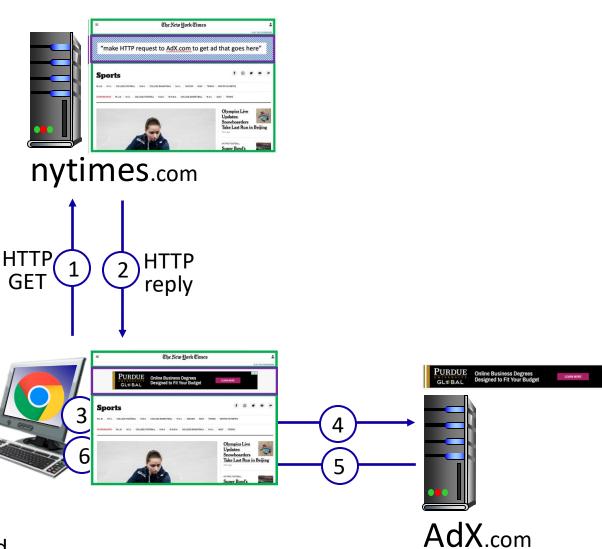

aside

cookies and privacy:

- cookies permit sites to learn a lot about you on their site.
- third party persistent cookies (tracking cookies) allow common identity (cookie value) to be tracked across multiple web sites

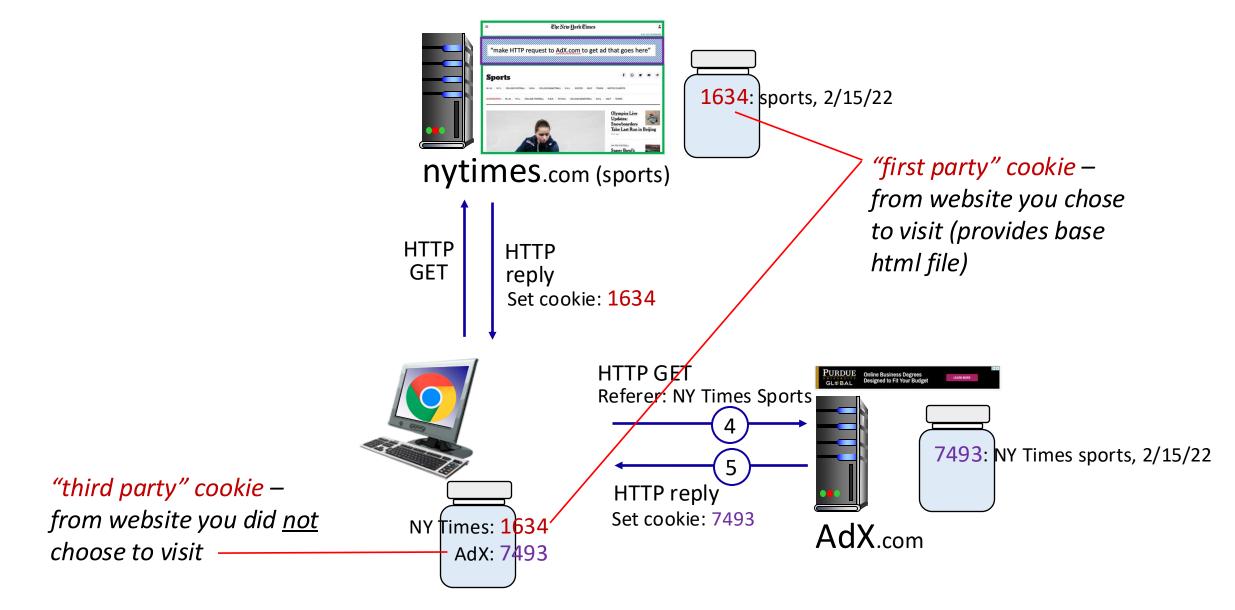

Example: displaying a NY Times web page

- GET base html file from nytimes.com
- fetch ad from AdX.com
- 7 display composed page

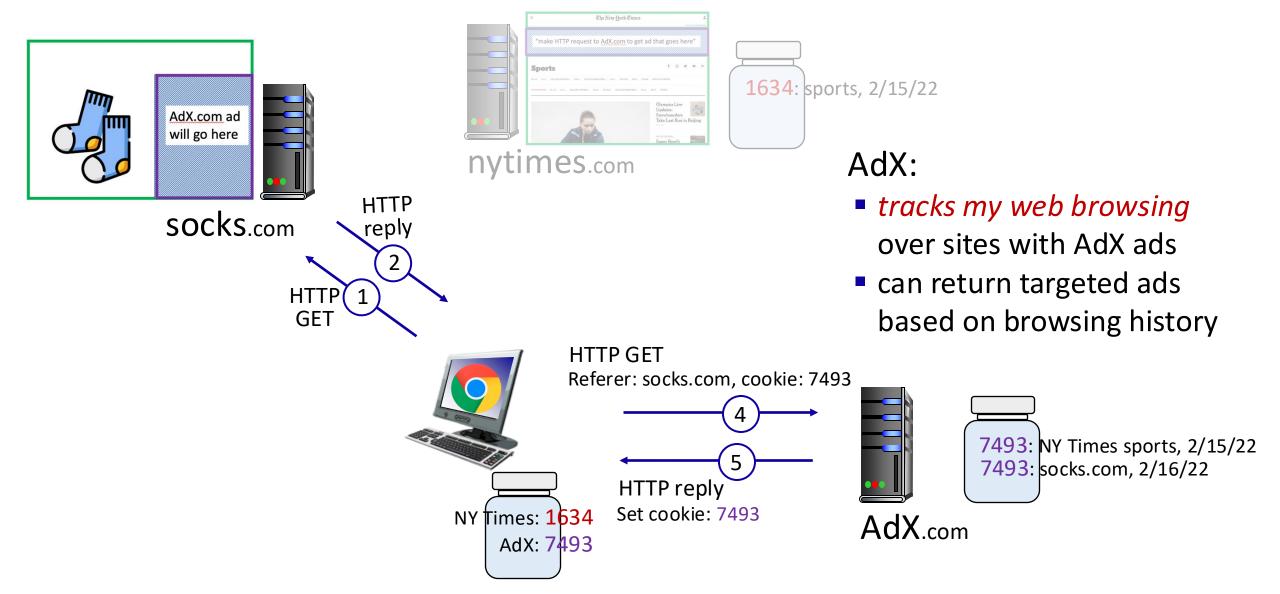

NY times page with embedded ad displayed

Cookies: tracking a user's browsing behavior

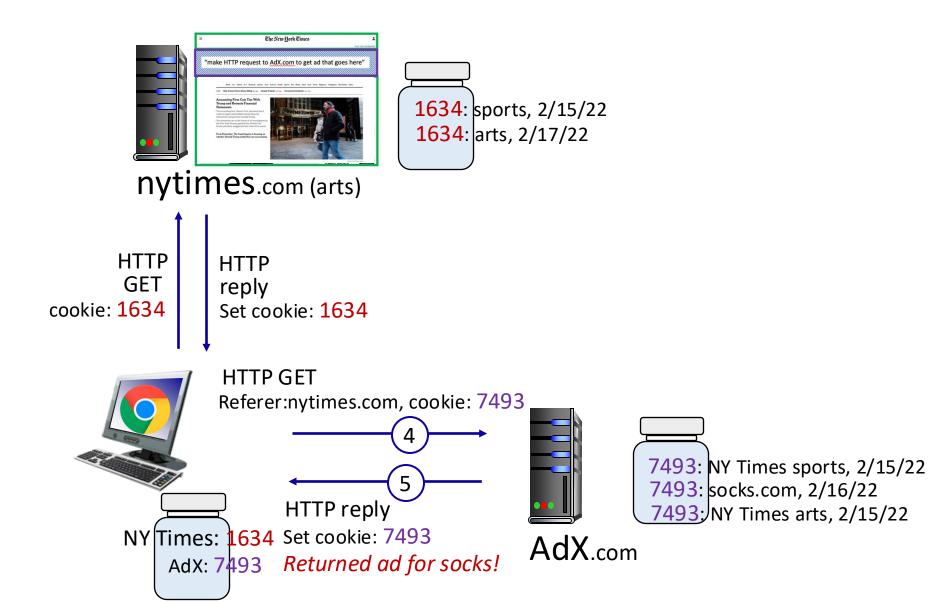

Cookies: tracking a user's browsing behavior

Cookies: tracking a user's browsing behavior (one day later)

Cookies: tracking a user's browsing behavior

Cookies can be used to:

- track user behavior on a given website (first party cookies)
- track user behavior across multiple websites (third party cookies)
 without user ever choosing to visit tracker site (!)
- tracking may be invisible to user:
 - rather than displayed ad triggering HTTP GET to tracker, could be an invisible link

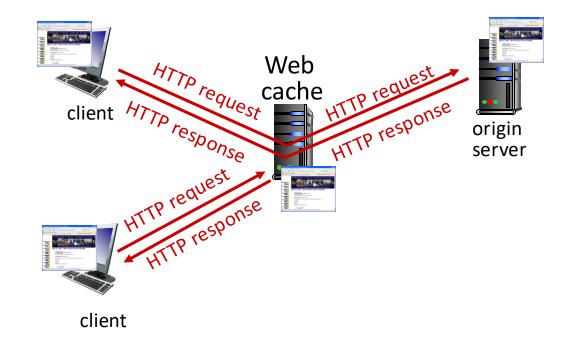

third party tracking via cookies:

Allow or disable in browsers, check the settings of Chrome,
 Firefox, Safari browsers

Web caches

Goal: satisfy client requests without involving origin server

- user configures browser to point to a (local) Web cache
- browser sends all HTTP requests to cache
 - *if* object in cache: cache returns object to client
 - else cache requests object from origin server, caches received object, then returns object to client

Web caches (aka proxy servers)

- Web cache acts as both client and server
 - server for original requesting client
 - client to origin server
- server tells cache about object's allowable caching in response header:

```
Cache-Control: max-age=<seconds>
```

Cache-Control: no-cache

Why Web caching?

- reduce response time for client request
 - cache is closer to client
- reduce traffic on an institution's access link
- Internet is dense with caches
 - enables "poor" content providers to more effectively deliver content

Caching example

Scenario:

- access link rate: 1.54 Mbps
- RTT from institutional router to server: 2 sec
- web object size: 100K bits
- average request rate from browsers to origin servers: 15/sec
 - avg data rate to browsers: 1.50 Mbps

Performance:

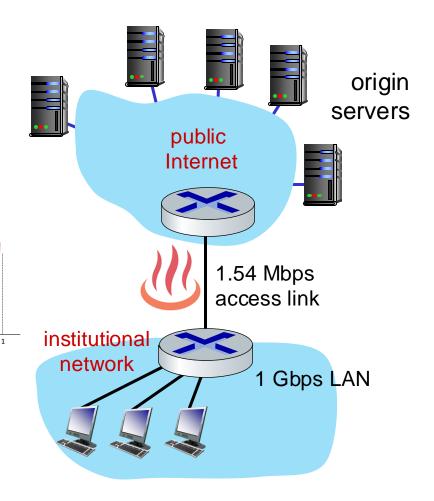

- access link utilization \(\int .97 \)
- LAN utilization: .0015

problem: large Large queueing delays

at high utilization!

end-end delay = Internet delay + access link delay + LAN delay

= 2 sec +(minutes)+ usecs

Option 1: buy a faster access link

Scenario:

,154 Mbps

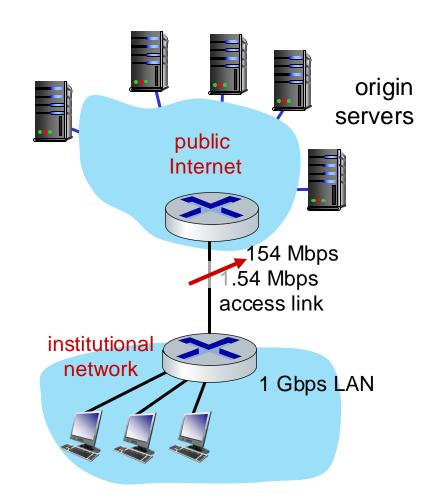

- access link rate: 1.54 Mbps
- RTT from institutional router to server: 2 sec
- web object size: 100K bits
- average request rate from browsers to origin servers: 15/sec
 - avg data rate to browsers: 1.50 Mbps

Performance:

- access link utilization = .97 → .0097
- LAN utilization: .0015
- end-end delay = Internet delay +
 access link delay + LAN delay
 = 2 sec + minutes + usecs

msecs

Cost: faster access link (expensive!)

Option 2: install a web cache

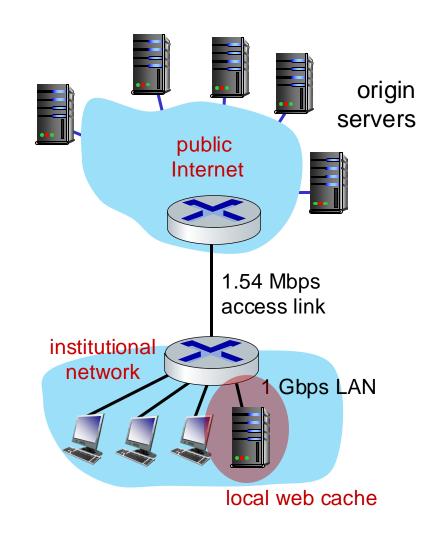

Scenario:

- access link rate: 1.54 Mbps
- RTT from institutional router to server: 2 sec
- web object size: 100K bits
- average request rate from browsers to origin servers: 15/sec
 - avg data rate to browsers: 1.50 Mbps

Cost: web cache (cheap!)

Performance:

- LAN utilization: .? How to compute link
 access link utilization = ? utilization, delay?
- average end-end delay = ?

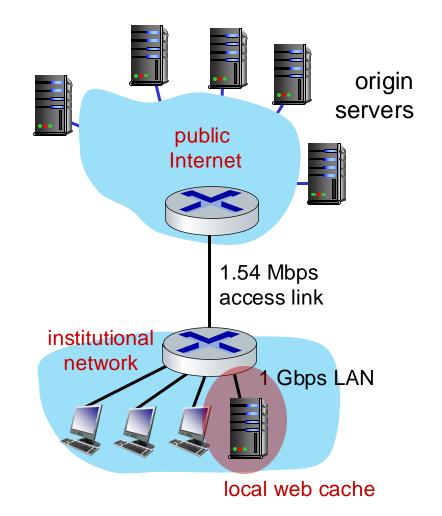

Calculating access link utilization, end-end delay with cache:

suppose cache hit rate is 0.4:

- 40% requests served by cache, with low (msec) delay
- 60% requests satisfied at origin
 - rate to browsers over access link

$$= 0.6 * 1.50 \text{ Mbps} = .9 \text{ Mbps}$$

- access link utilization = 0.9/1.54 = .58 means low (msec) queueing delay at access link
- average end-end delay:
 - = 0.6 * (delay from origin servers)+ 0.4 * (delay when satisfied at cache)
 - $= 0.6 (2.01) + 0.4 (^msecs) = ^1.2 secs$

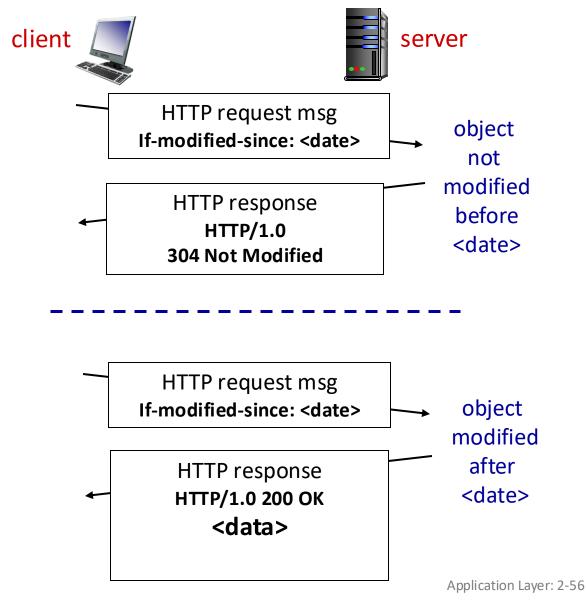

lower average end-end delay than with 154 Mbps link (and cheaper too!)

Browser caching: Conditional GET

Goal: don't send object if browser has up-to-date cached version

- no object transmission delay (or use of network resources)
- client: specify date of browsercached copy in HTTP request If-modified-since: <date>
- server: response contains no object if browser-cached copy is up-to-date:

HTTP/1.0 304 Not Modified

HTTP/2

Key goal: decreased delay in multi-object HTTP requests

<u>HTTP1.1:</u> introduced multiple, pipelined GETs over single TCP connection

- server responds in-order (FCFS: first-come-first-served scheduling) to GET requests
- with FCFS, small object may have to wait for transmission (head-of-line (HOL) blocking) behind large object(s)
- loss recovery (retransmitting lost TCP segments) stalls object transmission

HTTP/2

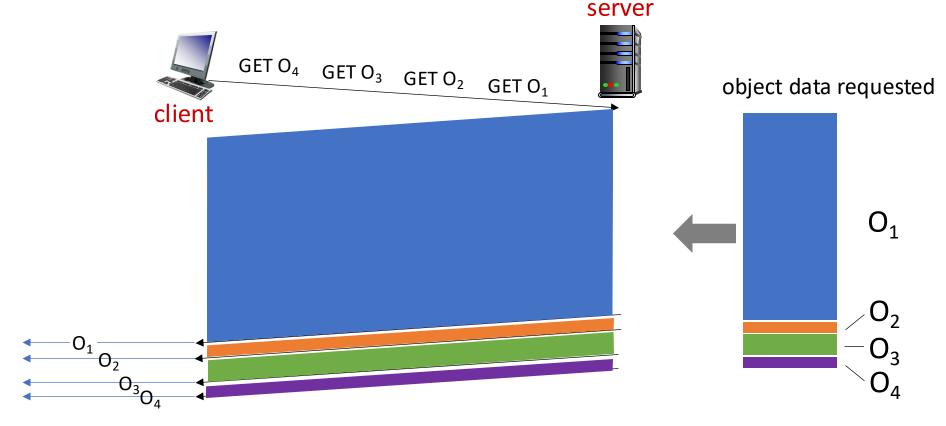

Key goal: decreased delay in multi-object HTTP requests

<u>HTTP/2:</u> [RFC 7540, 2015] increased flexibility at *server* in sending objects to client:

- methods, status codes, most header fields unchanged from HTTP 1.1
- transmission order of requested objects based on client-specified object priority (not necessarily FCFS)
- push unrequested objects to client
- divide objects into frames, schedule frames to mitigate HOL blocking

HTTP/2: mitigating HOL blocking

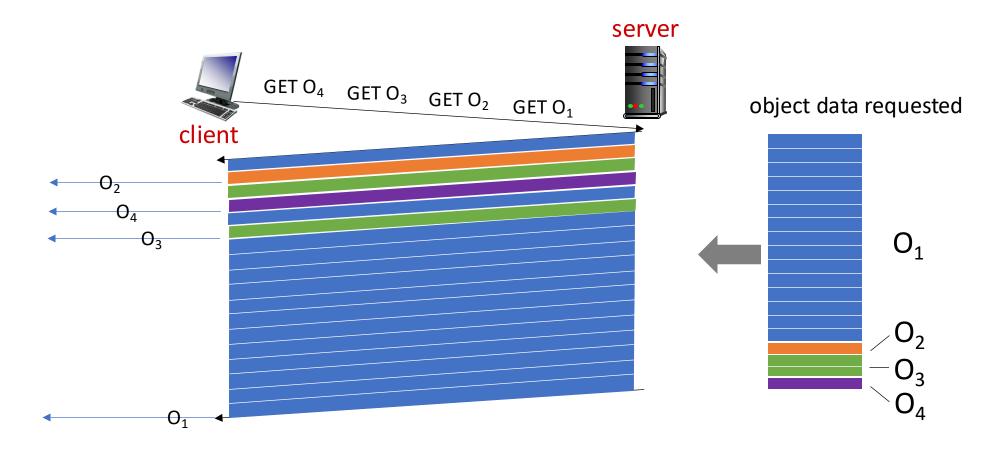

HTTP 1.1: client requests 1 large object (e.g., video file) and 3 smaller objects

objects delivered in order requested: O_2 , O_3 , O_4 wait behind O_1

HTTP/2: mitigating HOL blocking

HTTP/2: objects divided into frames, frame transmission interleaved

 O_2 , O_3 , O_4 delivered quickly, O_1 slightly delayed

HTTP/2 to HTTP/3

HTTP/2 over single TCP connection means:

- recovery from packet loss still stalls all object transmissions
 - as in HTTP 1.1, browsers have incentive to open multiple parallel
 TCP connections to reduce stalling, increase overall throughput
- no security over vanilla TCP connection
- HTTP/3 (optional): adds security, per object error- and congestion-control (more pipelining) over UDP
 - more on HTTP/3 in transport layer

Application layer: overview

- Principles of network applications
- Web and HTTP
- E-mail, SMTP, IMAP
- The Domain Name System DNS

- P2P applications
- video streaming and content distribution networks
- socket programming with UDP and TCP

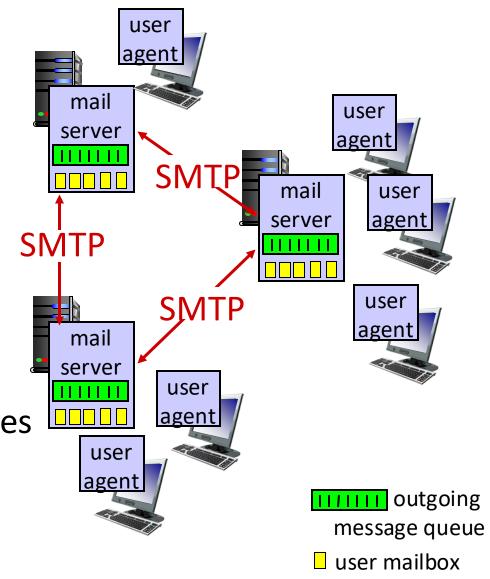

E-mail

Three major components:

- user agents
- mail servers
- simple mail transfer protocol: SMTP

User Agent

- a.k.a. "mail reader"
- composing, editing, reading mail messages
- e.g., Outlook, iPhone mail client
- outgoing, incoming messages stored on server

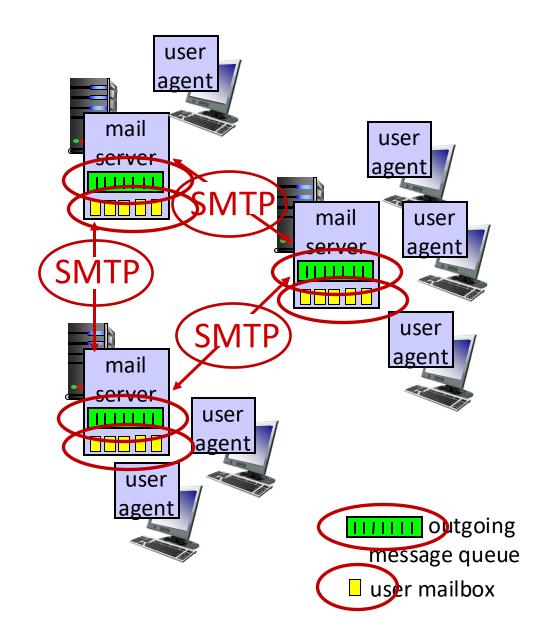

E-mail: mail servers

mail servers:

- mailbox contains incoming messages for user
- message queue of outgoing (to be sent) mail messages

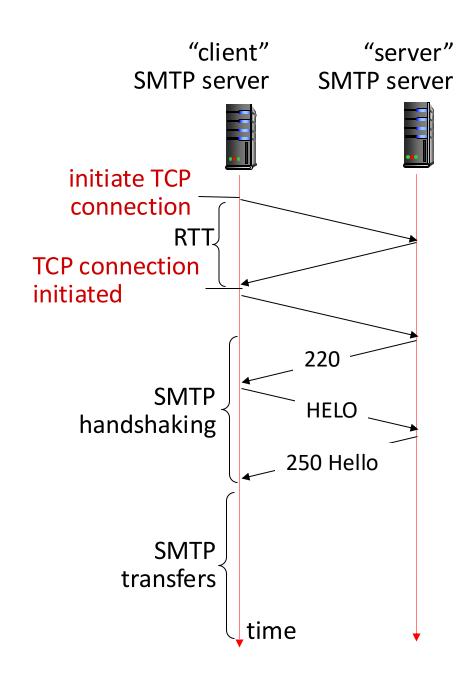

SMTP protocol between mail servers to send email messages

- client: sending mail server
- "server": receiving mail server

SMTP RFC (5321)

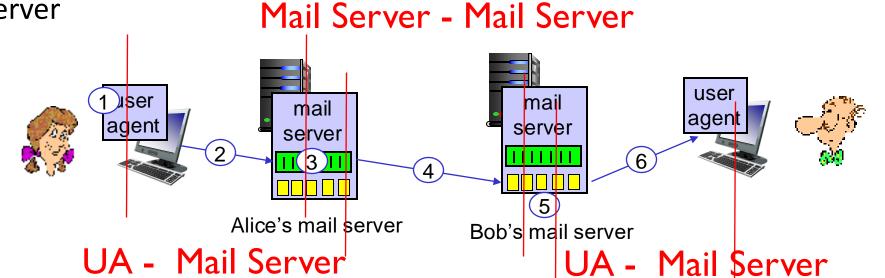

- uses TCP to reliably transfer email message from client (mail server initiating connection) to server, port 25
 - direct transfer: sending server (acting like client) to receiving server
- three phases of transfer
 - SMTP handshaking (greeting)
 - SMTP transfer of messages
 - SMTP closure
- command/response interaction (like HTTP)
 - commands: ASCII text
 - response: status code and phrase

Scenario: Alice sends e-mail to Bob

- 1) Alice uses UA to compose e-mail message "to" bob@someschool.edu
- 2) Alice's UA sends message to her mail server using SMTP; message placed in message queue
- 3) client side of SMTP at mail server opens TCP connection with Bob's mail server.

- 4) SMTP client sends Alice's message over the TCP connection
- 5) Bob's mail server places the message in Bob's mailbox
- 6) Bob invokes his user agent to read message

Sample SMTP interaction

S: 220 hamburger.edu

SMTP: observations

comparison with HTTP:

- HTTP: client pull
- SMTP: client push
- both have ASCII command/response interaction, status codes
- HTTP: each object encapsulated in its own response message
- SMTP: multiple objects sent in multipart message

- SMTP uses persistent connections
- SMTP requires message (header & body) to be in 7-bit ASCII
- SMTP server uses CRLF.CRLF to determine end of message

Mail message format

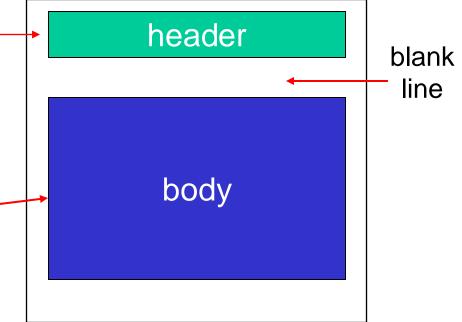

SMTP: protocol for exchanging e-mail messages, defined in RFC 5321 (like RFC 7231 defines HTTP)

RFC 2822 defines *syntax* for e-mail message itself (like HTML defines syntax for web documents)

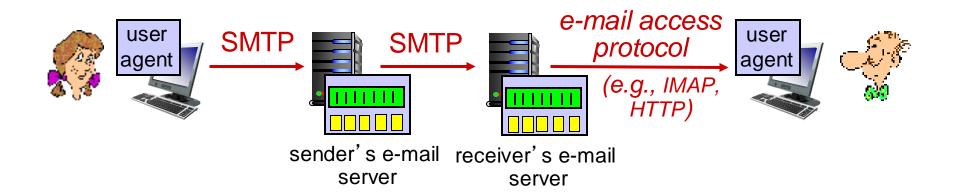

- header lines, e.g.,
 - To:
 - From:
 - Subject:

these lines, within the body of the email message area different from SMTP MAIL FROM:, RCPT TO: commands!

Body: the "message", ASCII characters only

Retrieving email: mail access protocols

- SMTP: delivery/storage of e-mail messages to receiver's server
- mail access protocol: retrieval from server
 - IMAP: Internet Mail Access Protocol [RFC 3501]: messages stored on server, IMAP provides retrieval, deletion, folders of stored messages on server
- HTTP: gmail, Hotmail, Yahoo!Mail, etc. provides web-based interface on top of STMP (to send), IMAP (or POP) to retrieve e-mail messages

Application Layer: Overview

- Principles of network applications
- Web and HTTP
- E-mail, SMTP, IMAP
- The Domain Name System DNS

- P2P applications
- video streaming and content distribution networks
- socket programming with UDP and TCP

DNS: Domain Name System

people: many identifiers:

SSN, name, passport #

Internet hosts, routers:

- IP address (32 bit) used for addressing datagrams
- "name", e.g., cs.umass.edu used by humans

Q: how to map between IP address and name, and vice versa?

Domain Name System (DNS):

- distributed database implemented in hierarchy of many name servers
- application-layer protocol: hosts, DNS servers communicate to resolve names (address/name translation)
 - note: core Internet function, implemented as application-layer protocol
 - complexity at network's "edge"

DNS: services, structure

DNS services:

- hostname-to-IP-address translation
- host aliasing
 - canonical, alias names
- mail server aliasing
- load distribution
 - replicated Web servers: many IP addresses correspond to one name

Q: Why not centralize DNS?

- single point of failure
- traffic volume
- distant centralized database
- maintenance

A: doesn't scale!

- Comcast DNS servers alone: 600B DNS queries/day
- Akamai DNS servers alone:2.2T DNS queries/day

Thinking about the DNS

humongous distributed database:

~ billion records, each simple

handles many trillions of queries/day:

- many more reads than writes
- performance matters: almost every Internet transaction interacts with DNS - msecs count!

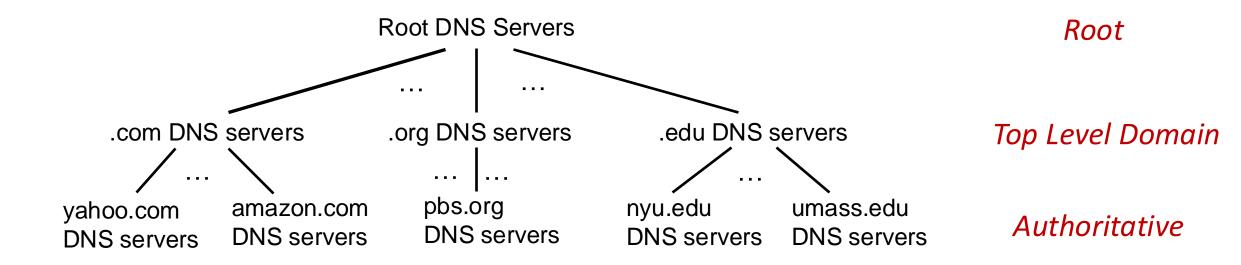

organizationally, physically decentralized:

 millions of different organizations responsible for their records

"bulletproof": reliability, security

DNS: a distributed, hierarchical database

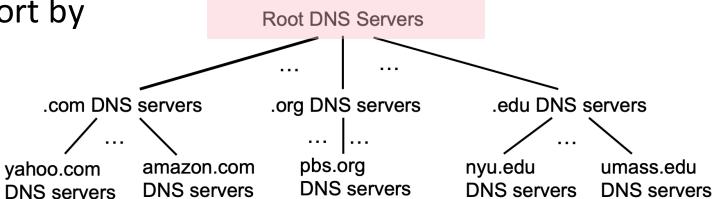

Client wants IP address for www.amazon.com; 1st approximation:

- client queries root server to find .com DNS server
- client queries .com DNS server to get amazon.com DNS server
- client queries amazon.com DNS server to get IP address for www.amazon.com

DNS: root name servers

 official, contact-of-last-resort by name servers that can not resolve name

DNS: root name servers

- official, contact-of-last-resort by name servers that can not resolve name
- incredibly important Internet function
 - Internet couldn't function without it!
 - DNSSEC provides security (authentication, message integrity)
- ICANN (Internet Corporation for Assigned Names and Numbers) manages root DNS domain

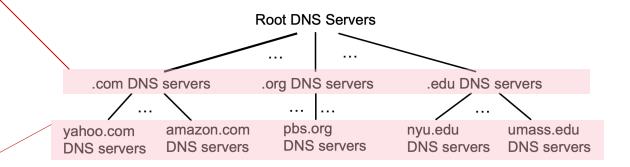

13 logical root name "servers" worldwide each "server" replicated many times (~200 servers in US)

Top-Level Domain, and authoritative servers

Top-Level Domain (TLD) servers:

- responsible for .com, .org, .net, .edu, .aero, .jobs, .museums, and all top-level country domains, e.g.: .cn, .uk, .fr, .ca, .jp
- Network Solutions: authoritative registry for .com, .net TLD
- Educause: .edu TLD

authoritative DNS servers:

- organization's own DNS server(s), providing authoritative hostname to IP mappings for organization's named hosts
- can be maintained by organization or service provider

Local DNS name servers

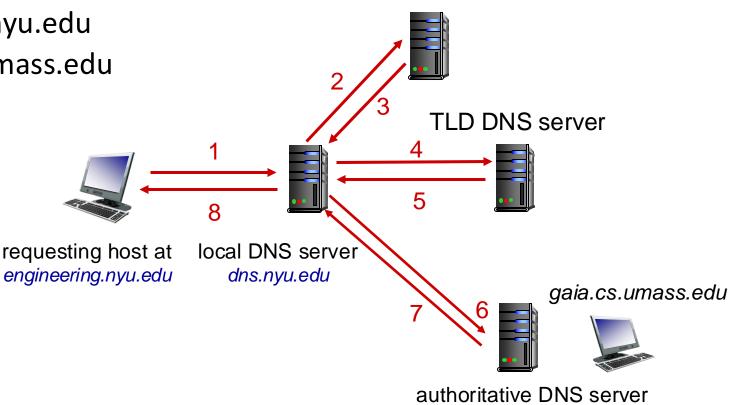

- when host makes DNS query, it is sent to its local DNS server
 - Local DNS server returns reply, answering:
 - from its local cache of recent name-to-address translation pairs (possibly out of date!)
 - forwarding request into DNS hierarchy for resolution
 - each ISP has local DNS name server; to find yours:
 - MacOS: % scutil --dns
 - Windows: >ipconfig /all
- local DNS server doesn't strictly belong to hierarchy

DNS name resolution: iterated query

Example: host at engineering.nyu.edu wants IP address for gaia.cs.umass.edu

Iterated query:

- contacted server replies with name of server to contact
- "I don't know this name, but ask this server"

root DNS server

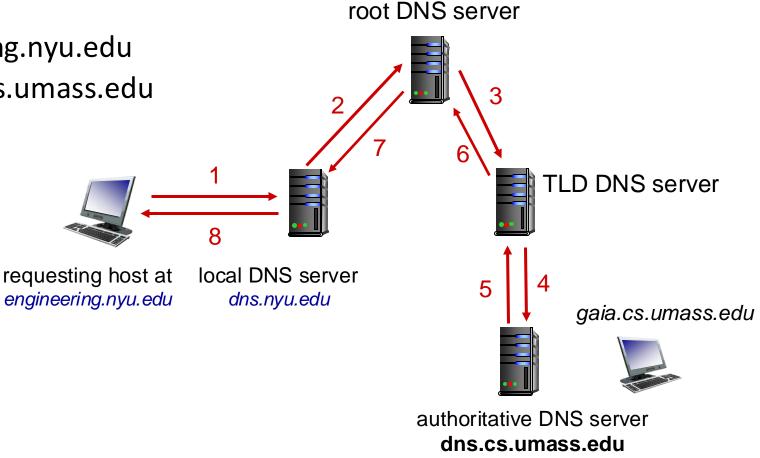

authoritative DNS server dns.cs.umass.edu

DNS name resolution: recursive query

Example: host at engineering.nyu.edu wants IP address for gaia.cs.umass.edu

Recursive query:

- puts burden of name resolution on contacted name server
- heavy load at upper levels of hierarchy?

Caching DNS Information

- once (any) name server learns mapping, it caches mapping, and immediately returns a cached mapping in response to a query
 - caching improves response time
 - cache entries timeout (disappear) after some time (TTL)
 - TLD servers typically cached in local name servers
- cached entries may be out-of-date
 - if named host changes IP address, may not be known Internetwide until all TTLs expire!
 - best-effort name-to-address translation!

DNS records

DNS: distributed database storing resource records (RR)

RR format: (name, value, type, ttl)

type=A

- name is hostname
- value is IP address

type=NS

- name is domain (e.g., foo.com)
- value is hostname of authoritative name server for this domain

type=CNAME

- name is alias name for some "canonical" (the real) name
- www.ibm.com is really servereast.backup2.ibm.com
- value is canonical name

type=MX

 value is name of SMTP mail server associated with name

Demo: Try DNS yourself (nslookup)

> nslookup www.cs.purdue.edu

Server: 128.210.11.57

Address:128.210.11.57#53

www.cs.purdue.edu canonical name = <u>pythia.cs.purdue.edu</u>.

Name: pythia.cs.purdue.edu

Address: <u>128.10.19.120</u>

More at demo-nslookup

Authoritative name servers

- > nslookup -type=NS cs.purdue.edu
- > nslookup -type=A harbor.ecn.purdue.edu

Canonical name (alias)

>nslookup -type=CNAME amazon.com

>nslookup -type=CNAME purdue.edu

Mail server

>nslookup -type=MX gmail.com

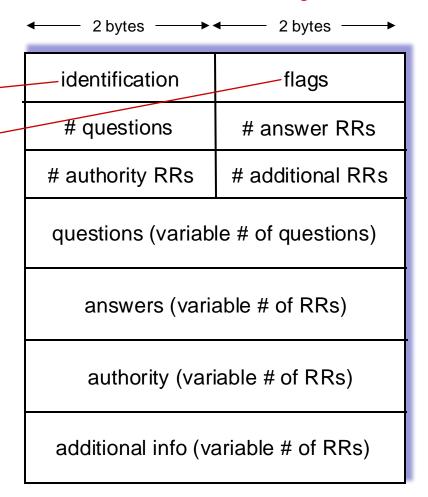

>nslookup -type=MX purdue.edu

DNS protocol messages

DNS query and reply messages, both have same format:

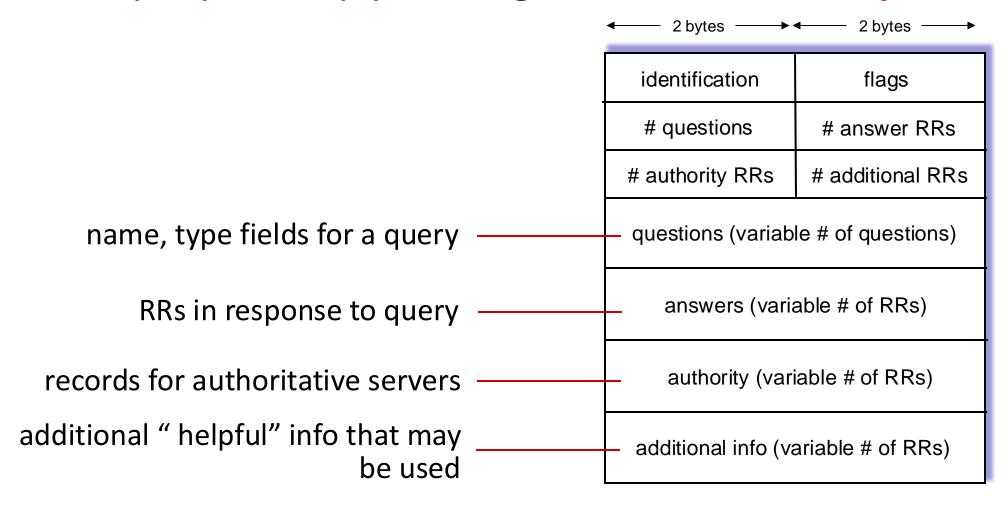

message header:

- identification: 16 bit # for query, reply to query uses same #
- flags:
 - query or reply
 - recursion desired
 - recursion available
 - reply is authoritative

DNS protocol messages

DNS query and reply messages, both have same format:

Getting your info into the DNS

example: new startup "Network Utopia"

- register name networkuptopia.com at DNS registrar (e.g., Network Solutions)
 - provide names, IP addresses of authoritative name server (primary and secondary)
 - registrar inserts NS, A RRs into .com TLD server:

```
(networkutopia.com, dns1.networkutopia.com, NS)
(dns1.networkutopia.com, 212.212.212.1, A)
```

- create authoritative server locally with IP address 212.212.212.1
 - type A record for www.networkuptopia.com
 - type MX record for networkutopia.com

Application layer: overview

- Principles of network applications
- Web and HTTP
- E-mail, SMTP, IMAP
- The Domain Name System DNS

- P2P applications
- video streaming and content distribution networks
- socket programming with UDP and TCP

Video Streaming and CDNs: context

- stream video traffic: major consumer of Internet bandwidth
 - Netflix, YouTube, Amazon Prime: 80% of residential ISP traffic (2020)
- challenge: scale how to reach ~1B users?
- challenge: heterogeneity
 - different users have different capabilities (e.g., wired versus mobile; bandwidth rich versus bandwidth poor)
- solution: distributed, application-level infrastructure

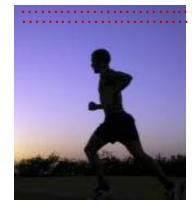

Multimedia: video

- video: sequence of images displayed at constant rate
 - e.g., 24 images/sec
- digital image: array of pixels
 - each pixel represented by bits
- coding: use redundancy within and between images to decrease # bits used to encode image
 - spatial (within image)
 - temporal (from one image to next)

spatial coding example: instead of sending N values of same color (all purple), send only two values: color value (purple) and number of repeated values (N)

frame i

temporal coding example: instead of sending complete frame at i+1, send only differences from frame i

frame i+1

Multimedia: video

- CBR: (constant bit rate): video encoding rate fixed
- VBR: (variable bit rate): video encoding rate changes as amount of spatial, temporal coding changes
- examples:
 - MPEG 1 (CD-ROM) 1.5 Mbps
 - MPEG2 (DVD) 3-6 Mbps
 - MPEG4 (often used in Internet, 64Kbps – 12 Mbps)

of sending N values of same color (all purple), send only two values: color value (purple) and number of repeated values (N)

frame i

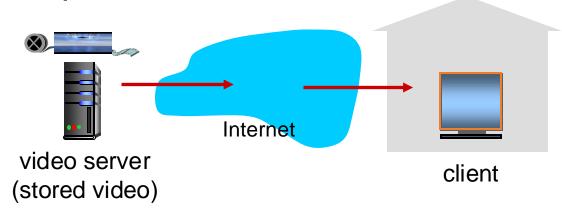

temporal coding example: instead of sending complete frame at i+1, send only differences from frame i

frame i+1

Streaming stored video

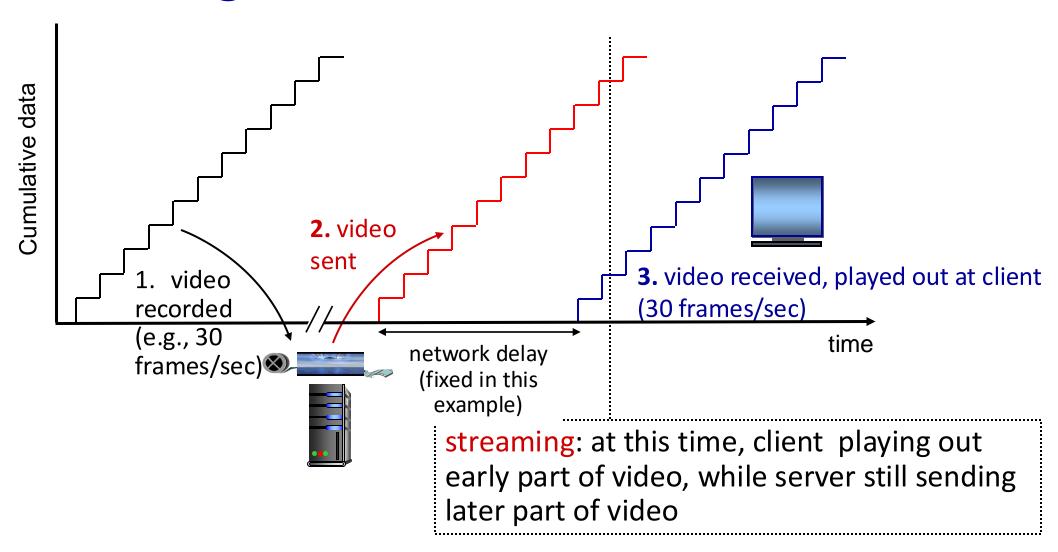

simple scenario:

Main challenges:

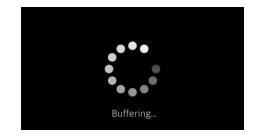

- server-to-client bandwidth will vary over time, with changing network congestion levels (in house, access network, network core, video server)
- packet loss, delay due to congestion will delay playout, or result in poor video quality

Streaming stored video

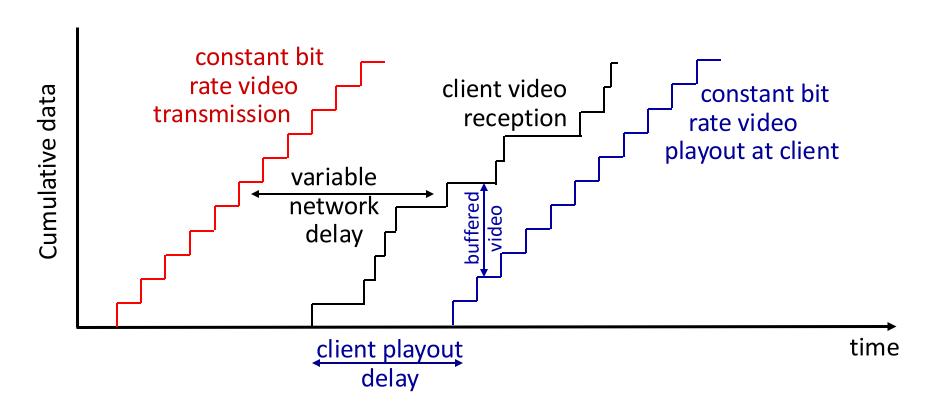

Streaming stored video: challenges

- continuous playout constraint: during client video playout, playout timing must match original timing
 - ... but network delays are variable (jitter), so will need client-side buffer to match continuous playout constraint

- other challenges:
 - client interactivity: pause, fast-forward, rewind, jump through video
 - video packets may be lost, retransmitted

Streaming stored video: playout buffering

 client-side buffering and playout delay: compensate for network-added delay, delay jitter

Streaming multimedia: DASH

Dynamic, Adaptive Streaming over HTTP

server:

- divides video file into multiple chunks
- each chunk encoded at multiple different rates
- different rate encodings stored in different files
- files replicated in various CDN nodes
- manifest file: provides URLs for different chunks

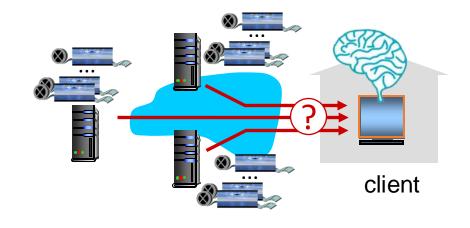

client:

- periodically estimates server-to-client bandwidth
- consulting manifest, requests one chunk at a time
 - chooses maximum coding rate sustainable given current bandwidth
 - can choose different coding rates at different points in time (depending on available bandwidth at time), and from different servers

Streaming multimedia: DASH

- "intelligence" at client: client determines
 - when to request chunk (so that buffer starvation, or overflow does not occur)
 - what encoding rate to request (higher quality when more bandwidth available)
 - where to request chunk (can request from URL server that is "close" to client or has high available bandwidth)

Streaming video = encoding + DASH + playout buffering

Streaming at Scale?

- challenge: how to stream content (selected from millions of videos) to hundreds of thousands of simultaneous users?
- Answer: content distribution networks (CDNs)
 - Cache in the middle or edge of the Internet
 - Optional: read 2.6.3 and 2.6.4
- Used by almost all the video streaming companies, e.g. Youtube, Netflix,

challenge: how to stream content (selected from millions of videos) to hundreds of thousands of simultaneous users?

- option 1: single, large "megaserver"
 - single point of failure
 - point of network congestion
 - long (and possibly congested) path to distant clients

....quite simply: this solution doesn't scale

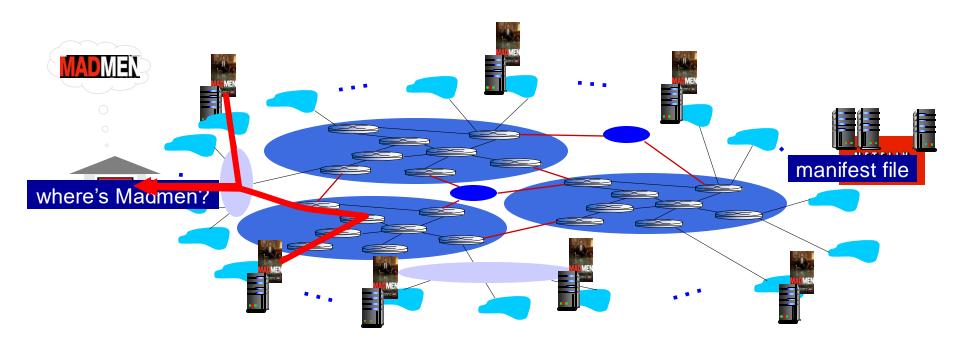

challenge: how to stream content (selected from millions of videos) to hundreds of thousands of simultaneous users?

- option 2: store/serve multiple copies of videos at multiple geographically distributed sites (CDN)
 - enter deep: push CDN servers deep into many access networks
 - close to users
 - Akamai: 240,000 servers deployed in > 120 countries (2015)
 - bring home: smaller number (10's) of larger clusters in POPs near access nets
 - used by Limelight

- CDN: stores copies of content (e.g. MADMEN) at CDN nodes
- subscriber requests content, service provider returns manifest
 - using manifest, client retrieves content at highest supportable rate
 - may choose different rate or copy if network path congested

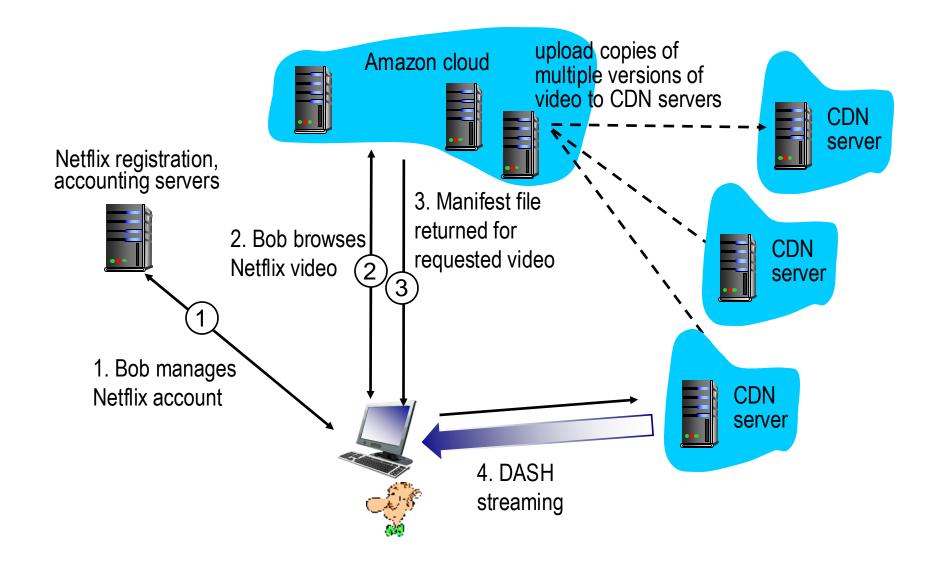

OTT challenges: coping with a congested Internet from the "edge"

- what content to place in which CDN node?
- from which CDN node to retrieve content? At which rate?

Case study: Netflix

Application layer: overview

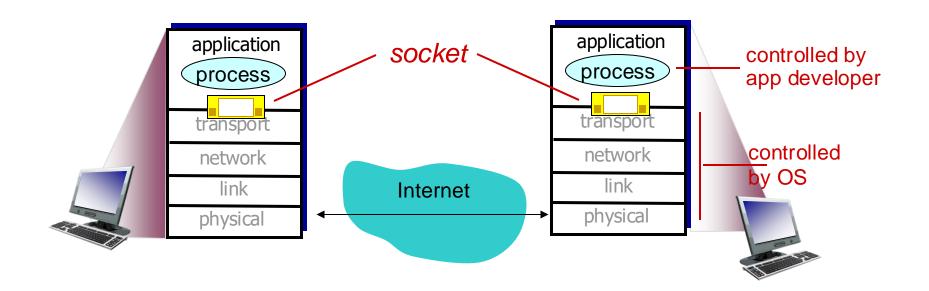

- Principles of network applications
- Web and HTTP
- E-mail, SMTP, IMAP
- The Domain Name System DNS

- P2P applications
- video streaming and content distribution networks
- socket programming with UDP and TCP (skipped)

Socket programming

goal: learn how to build client/server applications that communicate using sockets

socket: door between application process and end-end-transport protocol

Socket programming

Two socket types for two transport services:

- UDP: unreliable datagram
- TCP: reliable, byte stream-oriented Application Example:
 - client reads a line of characters (data) from its keyboard and sends data to server
 - 2. server receives the data and converts characters to uppercase
 - 3. server sends modified data to client
 - 4. client receives modified data and displays line on its screen

Socket programming with UDP

UDP: no "connection" between client & server

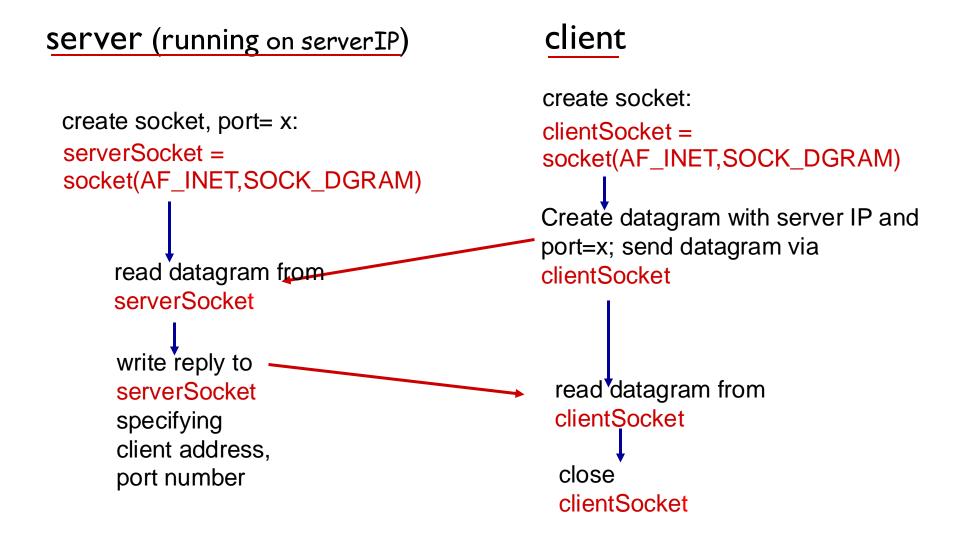

- no handshaking before sending data
- sender explicitly attaches IP destination address and port # to each packet
- receiver extracts sender IP address and po t# from received packet

UDP: transmitted data may be lost or received out-of-order

Application viewpoint:

■ UDP provides *unreliable* transfer of groups of bytes ("datagrams") between client and server

Client/server socket interaction: UDP

Example app: UDP client

Python UDPClient

```
include Python's socket
                        from socket import *
library
                        serverName = 'hostname'
                        serverPort = 12000
                        clientSocket = socket(AF_INET,
create UDP socket for
                                                SOCK_DGRAM)
server
                         message = raw input('Input lowercase sentence:')
get user keyboard
                       clientSocket.sendto(message.encode(),
input
Attach server name, port to
                                                (serverName, serverPort))
message; send into socket
                         modifiedMessage, serverAddress =
                                                clientSocket.recvfrom(2048)
read reply characters from ----
socket into string
                        print modifiedMessage.decode()
                        clientSocket.close()
print out received string
and close socket
```

Example app: UDP server

Python UDPServer

```
from socket import *
                         serverPort = 12000
                         serverSocket = socket(AF_INET, SOCK_DGRAM)
create UDP socket
                         serverSocket.bind((", serverPort))
bind socket to local port
number 12000
                         print ("The server is ready to receive")
                         while True:
loop forever
                            message, clientAddress = serverSocket.recvfrom(2048)
                            modifiedMessage = message.decode().upper()
Read from UDP socket into
message, getting client's
                            serverSocket.sendto(modifiedMessage.encode(),
address (client IP and port)
                                                  clientAddress)
 send upper case string
 back to this client
```

Socket programming with TCP

client must contact server

- server process must first be running
- server must have created socket (door) that welcomes client's contact

client contacts server by:

- Creating TCP socket, specifying IP address, port number of server process
- when client creates socket: client TCP establishes connection to server TCP

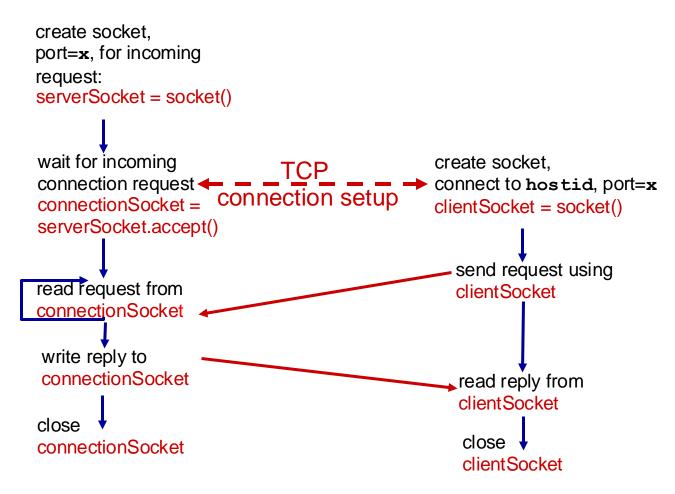

- when contacted by client, server
 TCP creates new socket for server
 process to communicate with that
 particular client
 - allows server to talk with multiple clients
 - source port numbers used to distinguish clients (more in Chap 3)

application viewpoint:

TCP provides reliable, in-order byte-stream transfer ("pipe") between client and server

Client/server socket interaction:TCP

server (running on hostid) client

Example app:TCP client

Python TCPClient

```
from socket import *
                        serverName = 'servername'
                        serverPort = 12000
create TCP socket for
                        clientSocket = socket(AF_INET, SOCK_STREAM)
server, remote port 12000
                        clientSocket.connect((serverName, serverPort))
                        sentence = raw_input('Input lowercase sentence:')
                        clientSocket.send(sentence.encode())
No need to attach server
                        modifiedSentence = clientSocket.recv(1024)
name, port
                        print ('From Server:', modifiedSentence.decode())
                        clientSocket.close()
```

Example app: TCP server Python TCP Server

```
from socket import *
                         serverPort = 12000
create TCP welcoming
                         serverSocket = socket(AF_INET,SOCK_STREAM)
socket
                         serverSocket.bind((",serverPort))
                         serverSocket.listen(1)
server begins listening for
                         print 'The server is ready to receive'
incoming TCP requests
                         while True:
   loop forever
                             connectionSocket, addr = serverSocket.accept()
server waits on accept()
for incoming requests, new
                             sentence = connectionSocket.recv(1024).decode()
socket created on return
                             capitalizedSentence = sentence.upper()
                            connectionSocket.send(capitalizedSentence.
 read bytes from socket (but
                                                                   encode())
 not address as in UDP)
                             connectionSocket.close()
close connection to this
client (but not welcoming
socket)
```

Chapter 2: Summary

our study of network application layer is now complete!

- application architectures
 - client-server
 - P2P
- application service requirements:
 - reliability, bandwidth, delay
- Internet transport service model
 - connection-oriented, reliable: TCP
 - unreliable, datagrams: UDP

- specific protocols:
 - HTTP
 - SMTP, IMAP
 - DNS
 - P2P: BitTorrent
- video streaming, CDNs
- socket programming:TCP, UDP sockets
