Lecture 12

A few other notes about variable elimination without Pivoting.
* Elements of U and L inverse
* Eliminating a block of variables.

Variable elimination with Pivoting!

Then Variable elimination for least squares problems.

- No PA=LU Problem I cannot
- office hours cancelled today
  —I'll stay on however

Last time

$A = L_1^{-1} \cdots L_{n-1}^{-1} L_n^{-1} U_n = U_1^{-1} \cdots$

$L_i = \begin{bmatrix} I & 0 & 0 \\ 0 & 1 & 0 \\ 0 & a & I \end{bmatrix}$

Goal this: show $L_1^{-1} \cdots L_{n-1}^{-1}$ is easy to compute. Then the $L = I + U_1 U_2^T$

$U_i = \begin{bmatrix} U_1 & 0 \\ 0 & 0 \end{bmatrix}$ U_1 is $i \times i$, U_2 is $n \times i$

$L_1 = \begin{bmatrix} I & 0 & 0 \\ 0 & 1 & 0 \\ 0 & a & I \end{bmatrix}$

$U_1 = \begin{bmatrix} e_1 \\ 0 \end{bmatrix}$

Now show $L_1^{-1} = I - U_1 U_2^T$

$(I - U_1 U_2^T)(I + U_1 U_2^T) = I + U_1 U_2^T - U_1 U_2^T - U_1 U_2^T U_1 U_2^T = I + U_1 U_2^T - U_1 (U_2^T U_1) U_2^T = I$ since $U_2^T U_1 = 0$

$L_1 \cdots L_{n-1} =$ from last step

$A = \begin{bmatrix} \alpha & c^T \\ d & R \end{bmatrix}$

$L_1 = \begin{bmatrix} 1 & 0 \\ d & I \end{bmatrix}$

$U_1 = \begin{bmatrix} e_1 \\ 0 \end{bmatrix}$

Now show $L_1^{-1} = I - U_1 U_2^T$

$(I - U_1 U_2^T)(I + U_1 U_2^T) = I + U_1 U_2^T - U_1 U_2^T - U_1 U_2^T U_1 U_2^T = I$ since $U_2^T U_1 = 0$

$L_1^{-1} \cdots L_{n-1}^{-1} =$

$I - U_2 e_1^T - U_3 e_2^T - \cdots - U_n e_{n-1}^T$

$L_i^{-1} \cdots L_{n-1}^{-1}$ is "easy" if $j > i$

$(I - U_i e_i^T)(I - U_j e_j^T) =$

$I - U_i e_i^T - U_j e_j^T + U_i e_i^T U_j e_j^T =$

$I - U_i e_i^T - U_j e_j^T$

$L_1^{-1} \cdots L_{n-1}^{-1} =$

$I - U_2 e_1^T - U_3 e_2^T - \cdots - U_n e_{n-1}^T$

$L = L_1^{-1} \cdots L_{n-1}^{-1}$ is lower tri.

The same holds for U, U_i (upper tri.)

```
function myreduce_all(A::Matrix)
  A = copy(A) # save a copy
  n = size(A,1)
  L = Matrix(1.0I,n,n)
  U = Matrix(1.0I,n,n)
  d = zeros(n)
  for i=1:n-1
    α = A[i,i]
    d[i] = α
    U[i+1:end,i] = A[i,i+1:end]/α
    L[i+1:end,i] = A[i+1:end,i]/α
    A[i+1:end,i+1:end] -= A[i+1:end,i]*A[i,i+1:end]'/α
  end
  d[n] = A[n,n]
  return L,U,d
end
```

$A = LOU$

This is called the LDU factorization

Next lecture with $A = L(OU)$, U.

The idea generalizes

$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} X_1 \\ X_2 \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \end{bmatrix}$ $\begin{matrix} n_1 \\ n_2 \end{matrix}$

$A_{11} X_1 + A_{12} X_2 = b_1$

$A_{21} X_1 + A_{22} X_2 = b_2$

If A_{11} is non-sing then

$X_1 = A_{11}^{-1}(b_1 - A_{12} X_2)$

$A_{21} A_{11}^{-1}(b_1 - A_{12} X_2) + A_{22} X_2 = b_2$

$(A_{22} - A_{21} A_{11}^{-1} A_{12}) X_2 = b_2 - A_{21} A_{11}^{-1} b_1$

$\rightarrow$ is called a Schur Complement.

I can Compute $A_{22} - A_{21} A_{11}^{-1} A_{12}$ if A_{11} is non-sing.

M steps of the Single Step elimination.

The final thing to say.

The operations to write

$X = S_{22}^{-1} T_2$.

So to solve $\begin{bmatrix} I & 0 \\ S & I \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \end{bmatrix}$

$T = \begin{pmatrix} \text{no} \\ \text{mo} \end{pmatrix} \begin{bmatrix} \text{no} & \text{mo} \\ I & \end{bmatrix}$

Oh by the way!

$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 5 \\ 6 \end{bmatrix}$

$\frac{0}{0}$

Quit $y = 5$ =>

$x = \begin{pmatrix} 5 - y \\ 6 \end{pmatrix}$ =>

Result: $\begin{pmatrix} ? \\ 6 \end{pmatrix}$

To fix this, we Swap rows!

$x + y = 6 \Rightarrow$

$x = 6 - y$.

The idea of pivoting is to reorder the rows of A to make sure we can always eliminate x_i as Step i.

Result: the n always possible.

If A_{11} is non-sing $\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{matrix} n_1 \\ n_2 \end{matrix}$

$\begin{bmatrix} I & 0 \\ -A_{21} A_{11}^{-1} & I \end{bmatrix} \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} - A_{21} A_{11}^{-1} A_{12} \end{bmatrix}$

$= \begin{bmatrix} A_{11} & A_{12} \\ 0 & S_{22} \end{bmatrix}$ S_{22} is non-sing.

If I can find a row of R where $R_{j1} \neq 0$. then the first col of $E = 0$.

The idea is: find a row where $R_{j1} \neq 0$ then Swap row i and j. (Or R, and all L's of the L_i's)

Last thing: we wrote

$PA = LOU$

Because "if A is then"

How do we do this for Least Sq?

$\min \|Ax - b\|_2$

$A : m \times n$, $L : n$-vectors $m > n$

$A = \begin{bmatrix} & \\ & \\ & \end{bmatrix}$ tall / over Constrained

A Pill rank =>

$Ax = 0 \Leftrightarrow x = 0$.

Look the variable elimin

$x = \begin{pmatrix} x_1 \\ y \end{pmatrix}$ Yield.

$A = \begin{bmatrix} A & C \end{bmatrix}$

$\min \|b - Ay - Cy\|_2^2$

Assume y is known.

Solve for x.

$\min \| b - Cy - Ay \|_2$

$\min \|d - gy\|_2$

Least Sq find Closest gy to d

Ques: What is y?

Solu:

y_1 is closest to $(d - gy) \perp a$

$g^T(d - gy) = 0$

$g \cdot \frac{a^T d}{a^T g} = y$

or Normal Eq $\min \|b - Ay\|_2$

$A^T y = A^T b$

$g(y) = \frac{a^T(b - Cy)}{a^T g}$

$\min \|b - Cy - Ay\|$

$b - Cy = \frac{a\,(a^T(b - Cy))}{a^T g}$

$b - \frac{a a^T b}{a^T g} = (y + \frac{a a^T}{a^T g} C y$

$\left(I - \frac{a a^T}{a^T g}\right) b = \left(I - \frac{a a^T}{a^T g}\right) C y$

CS 515 - Purdue University - Computer Science - David F. Gleich - 2019

$\min \|b - Ax\|_2 \quad n \times 1$

$A = [a \;\; A']$

$\Downarrow$

$\min \| (I - \frac{aa^T}{a^Ta})b - (I - \frac{aa^T}{a^Ta})Ax \|_2 \quad A'x(n-1)$

dim prob.

```
function least_squares_eliminate(A,b)
    a = A(:,1)
    na = norm(a)
    a = a/na
    if size(A,2) == 1
        return (a'*b)/na
    end
    y = least_squares_eliminate(A(:,2:end)-a'*a'*A(:,2:end), b - a'*a'*b)
    x = a'*(b - A(:,2:end)*y)/na
    return push!(x,y)
end
```

A more general approach
Use an Least Sq.

What is the closest point in span(A) to b?

A solution is

$A^T(b - Ax) = 0$

$A^Tb = A^TAx$
