Lecture 28

- Subspace iteration: get all the eigenvalues & vectors at once!

- The QR method is subspace iteration started from the identity.

- We can make this more efficient by reducing the matrix to a tridiagonal matrix first.

- Reduce the number of iterations? See the books. Shift and invert.

- Eigenvalues of sparse matrices. How we can use the Lanczos method to get good estimates.

- How ARPACK works. (The sparse solver in Matlab and Julia.)

Hill-Mahoged Fruits

÷ = div

Subspace iteration

Given A

Choose random $X^{(0)}$

for $k = 0, h, \ldots$

$Y = AX^{(k)}$

$QR = qr(Y)$ — reorder → $X^{(k+1)} = Q$

Power method: $x^{(k+1)} = Ax^{(k)}$ — normalize

for $k = 0, h, \ldots$

$y = Ax^{(k)}$

$x^{(k+1)} = \frac{y}{\text{normalize}(y)}$

$X^{(0)} = I$

Lots different methods!

Subspace

Given A

$X_0 = I$

for $i = 1$ to $\ldots$

$Y = AX_{i-1}$

$X, R_i = qr(Y)$

QR

Given A

Let $A_1 = A$

for $i = 1$ to $\ldots$

$Q_i, R_i = qr(A_i)$

$A_{i+1} = R_i Q_i$

Note! Reorder $R_i = Q_i^T A_i$ so $R_i Q_i = Q_i^T A_i Q_i$

→ So Eval A_i is the Same Evals

Lanczos

$X_i = G_i - Q_i$

Base Case: Skipped

$Q_1 = qr(A) = qr(A)$

(Same as Eval)

Induction Hypothesis

$X_i = Q_i - Q_i$

Subspace

$Y = AX_i$

$QR(Y) = qr(AQ_i - Q_i)$

$X_{i+1} = qr(AX_i) = qr(AQ_i - Q_i)$

$R_{i+1} = X_i^T A Q_i - Q_i$

Want to show $X_{i+1} \perp Q_i - Q_i$

$Q_{i+1}^T A Q_i - Q_i^T Q_i = 0$

$Q_{i+1}^T A Q_i - Q_i = 0$

$Q_{i+1}^T A Q_i = Q_i$

$X_{i+1} \perp Q_i - Q_i$

QR

$A_{i+1} = Q_i^T A Q_i$ where i

$= Q_i^T (Q_i - Q_i) A Q_i$

$= Q_i^T A Q_i - Q_i^T Q_i A Q_i$

$A_{i+1} = X_i^T A X_i$

$Q_{i+1} R_{i+1} = qr(X_i^T A X_i)$

$R_{i+1} = Q_i^T X_i^T A X_i$

(upper tri)

$\Rightarrow$

$Q_i^T Q_{i+1} R_{i+1} = X_i^T A X_i$

(by "uniqueness of QR")

Now: $A = X_i^T A X_i$

$\Rightarrow$ diag rules

$\Rightarrow$ X-rules.

What to remember?

$O(n^3)$ per iteration

If A is tridiag then $qr(A)$ can be done with Qx!

Gives Rahdorf!

If A is tridiag (sym)

Q_1: $\begin{bmatrix} x & & \\ x & x & \\ & & 1 \\ & & & 1 \end{bmatrix}$

Q_2: $\begin{bmatrix} 1 & & & \\ & x & x & \\ & x & x & \\ & & & 1 \end{bmatrix}$

$= R$

Start proof that RQ is tridiag.

A — tridiag, sym.

$QR = A \Rightarrow R = Q^T A$

$RQ = Q^T A Q$

$= $ sym.

$\Rightarrow RQ$ is tridiag if RQ is upper-Hessenberg.

$RQ = \begin{bmatrix} R \\ x\,x\,x \\ 0\,x\,x\,x \\ 0\,0\,x\,x\,x \\ 0\,0\,0\,x\,x \end{bmatrix} \begin{bmatrix} x & x & & & \\ x & x & x & & \\ & x & x & x & \\ & & x & x & x \\ & & & x & x \end{bmatrix}$

$\begin{bmatrix} x & x & & & \\ x & x & x & & \\ & x & x & x & \\ & & x & x & x \\ & & & x & x \end{bmatrix}$

$\begin{bmatrix} 1 & & & & \\ & x & x & & \\ & x & x & x & \\ & & x & x & x \\ & & & x & x \end{bmatrix}$

$\begin{bmatrix} 1 & & & & \\ & 1 & & & \\ & & x & x & \\ & & x & x & x \\ & & & x & x \end{bmatrix}$

$\begin{bmatrix} 1 & & & & \\ & 1 & & & \\ & & 1 & & \\ & & & x & x \\ & & & x & x \end{bmatrix}$

in each of 1/2

Last part: How to make Sym A into tridiag A and keep λ-val info (and Eigenvector info) fast

$x^T A x$ = tridiag

$Q^T A Q$ = tridiag. for any Q.

$\Rightarrow$ Use Lanczos!

Instead we will use Householder! (Also Sym.)

$A \to Q^T A Q$ = tridiag

Idea 1:

A

$Q^T A$

Idea 2: be Clever Google!

$Q^T A$

$Q^T A Q$

$Q^T A Q_1 = ?$

Observe the Pattern (!!)

$Q_2^T Q_1^T A Q_1 Q_2 =$

tridiag! (!!)

How ARPACK works?

Use implicit λ's of A.

Run Lanczos for $p > k$ iter. steps

$A \to V_{p+1} T_{p+1}$ — tridiag

Extract λ's of A are λ's of T_p in $\begin{bmatrix} T_p \\ \cdots \end{bmatrix}$

$p > k$

Implicit Restart

$V_{p+1}^{(1)} T_{p+1}^{(1)}$

$\vdots$

$V_{p+1}^{(k)} T_{p+1}^{(k)}$

$\vdots$

Converge when λ's stop changing.
