Lecture 14

Overview of unconstrained optimization algorithms (Handout from last time)

Line search methods
Descent directions
What goes wrong (and how it differs from univariate)
How to fix it: Wolfe conditions, i.e. goldilocks conditions.

Proof that we can do this (if time)

Terms:
Descent direction
Wolfe conditions
Sufficient decrease (Armijo condition)
Curvature condition
Strong Wolfe conditions

Midterm: March 13th (in class)

Back to min Prob

$\min_{x \in \mathbb{R}^n} f(x)$

Assume twice cont diff

2nd order Necessary cond.

$\nabla f(x^*) = 0 \qquad H(x^*) \geq 0$

2nd order Suff cond.

$\nabla f(x^*) = 0 \qquad H(x^*) > 0$

All methods are iterative

$x^{(k)} \to x^{(new)}$

Line Search

Trust Region

Find p that $f(x^{(k)} + \alpha p) < f(x^{(k)})$

Find optimal $f(x)$ s.t. $\|x - x^{(k)}\| \leq \alpha$

Newton Method's

Be sure of positive definite!

$x^{(k)} = x^{(new)}$

$x^{(k)} = x^{(new)}$

$g = \nabla f(x^{(new)})$

$g^k = \nabla f(x^{(new)})$

$H^k = H(x_k)$

$H^k = H(x_{new})$

$f_k = f(x_k)$

$f^k = f(x_{new})$

i.e.

$f(x - \alpha g) =$

$f(x - \alpha * g(x_k))$

Line Search Methods

$x^k = x + \alpha p$

① Find p

② Find α

How to find p?

- Steepest gradient descent for $-g$
- gradient descent $p = -g$
- Newton. $p = -H^{-1}g$
- Quasi-Newton. Let $B \approx H$, then $p = -B^{-1}g$
- Conj. Grad

Practical calc for a LS method

While not done, (i.e. the gradient is big)

- Pick p as a search dir.
- Pick α as a step length
- Move $x \leftarrow x + \alpha p$

Key questions - How big α to take? How to pick p?

Goal: minimize $f(x)$

First, we will analyze descent directions that yield f small. (or)

Definition

A descent direction at x_k is a p s.t.

$g(\alpha) = f(x_k + \alpha p)$

$g'(0) < 0$.

Why only look at descent directions?

We can always find α^* smaller!

$f(x_k + \alpha p) =$

$f_k + \alpha \nabla f(x_k)^T p + O(\alpha^2)$

(By Taylor's theorem)

If p is small enough, then $\alpha^* < 0$.

Lemma Let B be a sym pos def matrix. Then any p s.t.

$B p = -g$

gives a descent dir. (Unless you are at a stationary pt. ⊕

Pf: $p = -B^{-1} g$

If B is pos def, then B^{-1} is too!

$g^T p = \underbrace{g^T B^{-1} g}_{> 0} < 0$

Eg. $n = 1$

$p = -g$

gradient descent

Eg. $B = I$

$p = -g$

gives a descent dir.

Unless $g = 0$

Pf: $g^T p = g^T(-g) = -\|g\|^2 < 0$

We always desire to find a descent direction!

Is a descent direction small enough to minimize f?

No!

1. Example 1.

$x_{k+1} = x_k + \alpha_k p_k$ Line Search.

Slope $= f'_k = \frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \ldots$

Yes! $x_k \to 0$

$x_k \to 0$, the $f(x_{k+1}) < f(x_k)$

Ex 2 will converge, but not actually converge to $x = 0$.

Ex 3 will converge to a saddle point.

The reason Ex 1 + 2 converge is because they take steps $\alpha_k \to 1$ but not $\alpha_k = 1$.

We take big steps but... only reduce f by a tiny amount.

So we need some condition to make progress in a meaningful way.

Goal: Look out for a condition on α st. we make progress toward a minimum & small enough that we don't step over it.

⊕ Need look to ensure $L(\alpha) \neq 0$

Just want to be small and very small.

Also we can compute $L'(\alpha) = \nabla f(x + \alpha p)^T p$

To avoid Unstable steps, $\alpha \to 0$

Use tools in log step of Should reach help min α small.

1. A Armijo Step 4
