### Lecture 09: Shamir Secret Sharing (Conclusion)

Shamir Secret Sharing

御 と く ヨ と く

### Shamir Secret Sharing: Recall

Setting

- Fix a finite field (ℤ<sub>ρ</sub>, +, ×)
- There are n parties such that n < p
- Reconstruction threshold is t

Secret Sharing Algorithm:

- Objective: Share a secret  $s \in \mathbb{Z}_p$
- Pick a random polynomial P(X) with Z<sub>p</sub> coefficients and degree < t such that P(0) = s</li>
- For  $i \in \{1, 2, ..., n\}$ , define the *i*-th secret share  $s_i := P(i)$

Secret Reconstruction Algorithm:

- Objective: Given shares  $(i_1, s_{i_1}), (i_2, s_{i_2}), \dots, (i_t, s_{i_t})$  where  $i_1, i_2, \dots, i_t$  are distinct, recover the secret
- Use Lagrange Interpolation to find the unique polynomial Q(X) of degree < t such that  $Q(i_1) = s_{i_1}$ ,  $Q(i_2) = s_{i_2}$ ,  $\ldots$ ,  $\overline{Q}(i_t) = s_{i_t}$
- Define the recovered secret to be Q(0)

High-level Overview

- Use the Graph-theoretic Representation Strategy
- Left Partite Set: Set of "Things that we intend to hide"

$$\left\{ \ (0,s) \colon s \in \mathbb{Z}_p \ \right\}.$$

• Right Partite Set: Set of "Things that an adversary sees"

$$\begin{cases} 0 \leqslant k < t \\ \left( (i_1, s_{i_1}), (i_2, s_{i_2}), \dots (i_k, s_{i_k}) \right) : \text{distinct } i_1, \dots, i_k \in \{1, 2, \dots, n\} \\ s_{i_1}, s_{i_2}, \dots, s_{i_k} \in \mathbb{Z}_p \end{cases}$$

• Witness: A polynomial (of degree < t) explaining an element of the left partite set and an element of the right partite set

#### Number of Witnesses

• The edge joining the following two vertices

You will prove this result in the homework

- Since the weight of any edge is independent of the left vertex, the scheme is secure
- Remark: The weight can depend on the vertex in the right partite set, which is permissible according to our security definition

### Additional Clarifications on the Graph Representation

Vertices in the right partite set.

- Fix any  $k \in \{0, 1, \dots, t-1\}$
- The total number of vertices of the form  $((i_1, s_{i_1}), (i_2, s_{i_2}), \dots, (i_k, s_{i_k}))$  are

$$\binom{n}{k} \cdot p^k$$

Explanation: There are  $\binom{n}{k}$  ways of choosing distinct  $i_1, \ldots, i_k$ . After that, there are  $p^k$  ways of choosing  $s_{i_1}, s_{i_2}, \ldots, s_{i_k}$ 

- In particular, if k = 0, then there is exactly one such vertex
- The total number of vertices in the right partite set, therefore, is:

$$\sum_{k=0}^t \binom{n}{k} \cdot p^k.$$

#### Shamir Secret Sharing

Example 1 for the weight of an edge.

- Suppose t = 3 (that is, any three parties can come together to reconstruct the secret)
- Shamir secret sharing uses polynomials with degree < t. So, any candidate polynomial f(X) is of the form

$$f_0 + f_1 \cdot X + f_2 \cdot X^2$$

Here, think of  $f_0, f_1, f_2$  as "degrees of freedom." This polynomial has 3 degrees of freedom.

Consider a left vertex (0, s). For k = 1, consider the right vertex (i<sub>1</sub>, s<sub>i<sub>1</sub></sub>).

• The weight of the edge connecting this left and right vertex above is the number of polynomials f(X) that satisfy f(0) = s and  $f(i_1) = s_{i_1}$ . So, we have the following two linear constraints:

Ш

$$f_0 + f_1 \cdot 0 + f_2 \cdot 0^2 = s$$
  
$$f_0 + f_1 \cdot i_1 + f_2 \cdot (i_1)^2 = s_{i_1}.$$

There are two linear constraints. In homework, you will prove that in such linear systems, if you begin with 3 degrees of freedom and add 2 constraints, you are left with only one degree of freedom. Therefore, the total number of  $(f_0, f_1, f_2)$  satisfying these constraints is  $p^{\text{remaining-degrees-of-freedom}} = p^1$ .

### Additional Clarifications on the Graph Representation

#### Example 1.1 for the weight of an edge.

- Let us elaborate more on the previous example.
- Suppose the left vertex is (0,5) and the right vertex is (3,7).
- So, the constraints are:

$$f_0 + f_1 \cdot 0 + f_2 \cdot 0^2 = 5$$
  
$$f_0 + f_1 \cdot 3 + f_2 \cdot 3^2 = 7$$

• The simultaneous solutions must satisfy  $f_0 = 5$  and  $3 \cdot f_1 + 9 \cdot f_2 = 2$ . So, the solutions are

$$\left(5, f_1, \frac{2-3 \cdot f_1}{9}\right).$$

For every choice of  $f_1$ , we get one solution. There are p such choices possible. Therefore, there are a total of p solutions; as expected.

# Additional Clarifications on the Graph Representation

### Example 2 for the weight of an edge.

- Consider a left vertex (0, s). For k = 2, consider the right vertex ((i<sub>1</sub>, s<sub>i1</sub>), (i<sub>2</sub>, s<sub>i2</sub>))
- We are interested in counting the number of polynomials  $f_0 + f_1 \cdot X + f_2 \cdot X^2$  that interpolate these three points.
- Any polynomial interpolating them must satisfy the following constraints.

$$f_0 + f_1 \cdot 0 + f_2 \cdot 0^2 = s$$
  

$$f_0 + f_1 \cdot i_1 + f_2 \cdot (i_1)^2 = s_{i_1}$$
  

$$f_0 + f_1 \cdot i_2 + f_2 \cdot (i_2)^2 = s_{i_2}$$

• So, the polynomial began with 3 degrees of freedom. After that, 3 constraints were added. Therefore, the remaining degrees of freedom is 3 - 3 = 0. Using the results proven in your homework, the number of solutions will be  $p^0 = 1$ .

# Additional Clarifications on the Graph Representation VI

#### Example 2.1 for the weight of an edge.

- Consider the left vertex (0,5) and the right vertex ( (3,7), (5,2) )
- So, the constraints are:

$$f_0 + f_1 \cdot 0 + f_2 \cdot 0^2 = 5$$
  

$$f_0 + f_1 \cdot 3 + f_2 \cdot 3^2 = 7$$
  

$$f_0 + f_1 \cdot 5 + f_2 \cdot 5^2 = 2.$$

• You can verify that the solution is

$$\left(5,\frac{77}{30},-\frac{19}{30}\right)$$

• There is only  $p^0 = 1$  solution, consistent with the calculation in example 2.

• • = • • = •

#### Extension to Correctness.

- Note that the right partite sets only contain vertices corresponding to k shares, where k ∈ {0, 1, ..., t − 1}
- It is natural to wonder what will happen if we have vertices in the right partite set with k = t shares!
- Suppose the right vertex is

$$((i_1, s_{i_1}), (i_2, s_{i_2}), \dots, (i_t, s_{i_t}))$$

Note that this vertex has t shares.

Note that those parties can reconstruct the unique secret polynomial of degree < t that interpolates these t points. After that, this reconstructed polynomial is either consistent with the left vertex (0, s) or not; there is no middle ground.</li>

- So, there is a unique left vertex  $(0, s^*)$  with which the reconstructed polynomial will be consistent. The weight of the edge joining that specific left vertex to the right vertex will be 1.
- For all left vertices (0, s), such that s ≠ s\*, the reconstructed polynomial will be inconsistent. The weight of the edge joining any of these left vertices with the right vertex will be 0.
- So, it is apparent that the weight depends on the left vertex in this case! Therefore, the scheme is "insecure" when t shares are revealed. This phenomenon is expected because t parties can reconstruct the secret. Intuitively, "reconstruction" entails "insecurity."

### Example 3 for correctness.

• Consider k = 3 and a right vertex

((1,0),(3,7),(5,2))

IX.

• These three points are sufficient to reconstruct the unique degree < 3 polynomial interpolating them. The constraints are

$$f_0 + f_1 \cdot 1 + f_2 \cdot 1^2 = 0$$
  
$$f_0 + f_1 \cdot 3 + f_2 \cdot 3^2 = 7$$
  
$$f_0 + f_1 \cdot 5 + f_2 \cdot 5^2 = 2$$

• Verify that the simultaneous solution is

$$(f_0, f_1, f_2) = \left(-8, \frac{19}{2}, -\frac{3}{2}\right)$$

Shamir Secret Sharing

向下 イヨト イヨト

• So, the reconstructed polynomial is

$$f(X) = (-8) + \frac{19}{2} \cdot X + \left(-\frac{3}{2}\right) \cdot X^2$$

X

This reconstructed polynomial is consistent only with the left vertex

$$(0, -8)$$

• So, the weight of the edge joining the left vertex (0, -8) with the right vertex will be 1. The weight of the edge joining the left vertex (0, s), where  $s \neq -8$ , with the right vertex will be 0
